Index—California and Western Medicine, Volume 46 January to June, 1937

INDEX ARRANGEMENT Sequence of Subheads in Index

- This index is arranged under the following headings:
- I. Authors.
 - II. Subjects—Titles of papers.
 - III. Editorials.
 - IV. Editorial Comment articles.
 - V. Bedside Medicine articles.
 - VI. Medical History articles.
 - VII. Miscellany columns.
 - VIII. California Medical Association.
 - (a) General.
 - (b) Component County Societies.
 - (c) Department of Public Relations.
 - (d) Woman's Auxiliary.
 - IX. Deceased Members.
 - X. Book Reviews.
 - XI. Report of Medical Examiners.

Key to Abbreviations in This Index

- Or.—Original Article.
- C. R.—Case Report.
- B. M.—Bedside Medicine.
- Ed.—Editorial.
- E. C.—Editorial Comment.
- C. N.—Clinical Notes.
- L. M. H.—Lure of Medical History.

Index to Pages, Volume 46, California and Western Medicine, January to June, 1937

Date of Issue	No. of Pages	Date of Issue	No. of Pages
January, 1937	1-72	April, 1937	217-288
February, 1937	73-144	May, 1937	289-360
March, 1937	145-216	June, 1937	361-448

Two Volumes Yearly

CALIFORNIA AND WESTERN MEDICINE is issued annually in two volumes: the first, from January to June, inclusive; and the second from July to December, inclusive.

American Medical Association Quarterly Cumulative Index

Members who wish to consult a general medical index are referred to the Quarterly Cumulative Index of the American Medical Association.

I AUTHORS—INDEX

A	PAGE	H	PAGE
Alderson, Harry E.—Dermatitis Venenata (B. M.)	185	Ginsburg, H. M.—Black Widow Spider Bite (Or.)	381
Arnold, Hubert R.—An Efficient Back Brace (C. N.)	323	Gosney, E. S.—Human Sterilization Today (Or.)	396
Askey, John Martin—Basal Metabolism (Or.)	11	Gray, J. P., and Geiger, J. C.—Influenza: The San Francisco Outbreak of January-February, 1937 (Or.)	379
Ayres, Samuel, Jr.—Dermatitis Venenata (B. M.)	183	Grishaw, William H., and Smith, Bernard—Protamin Insulin: Some Clinical Studies (Or.)	157
B			
Bakewell, Benjamin—Contraction Ring Dystocia: Treatment with Epinephrin (C. R.)	109	Hale, Nathan G.—Chronic Prostatitis (B. M.)	406
Barkan, Otto, Maisler, S.—Adrenalin Chlorid in 1:100 Strength in Ophthalmology (E. C.)	150	Hamilton, Paul M.—Immunotransfusion: Its Use in the Treatment of Communicable Diseases (Or.)	245
Barnard, Harold Dewey and Tucker, George E.—Expert Medical Testimony in California Courts (Or.)	95	Hanzlik, P. J.—The Extensive Side-Actions of Barbitals and Their Treatment (Or.)	302
Barnes, Roger W.—Chronic Prostatitis (B. M.)	407	Heissig, Ida—Peridural Anesthesia (Or.)	316
Bathurst, E. W.—Diphtheria in 1880: In Siskiyou County (L. M. H.)	179	Henderson, J. L., and Burns, G. Creswell—Bromid Intoxication (Or.)	392
Beach, Edward W.: The So-Called "Straddle" Injury: Its Management (Or.)	234	Howard, Campbell P.—Clinical Pathological Conference (Or.)	151
Preparation of Catheterization (B. M.)	263		
Behneman, Harold H. F.: Silicosis (Or.)	232	J	
The Whitman Centennial: The Late Dr. Marcus Whitman (L. M. H.)	319	Jones, Guy P.—The California State Board of Public Health (L. M. H.)	400
Berkley, Hugh K.—Convulsions in Children (B. M.)	45	K	
Bierman, Jessie M.—Acute Diffuse Glomerulonephritis (C. R.)	41	Kocher, R. A.—Anaphylaxis Following the Use of Pituitary Extract (C. R.)	262
Bird, Arthur A.—Convulsions in Children (B. M.)	45	Kreutzmann, Henry A. R.—Preparation of Catheterization (B. M.)	265
Bogen, Emil—Medical Aspects of the Business Cycle (Or.)	312	Kutzman, Adolph A.—Preparation of Catheterization (B. M.)	265
Botsford, Mary E.—Preanesthetic Drugs (B. M.)	116	L	
Brockway, A.—Osteomyelitis and Suppurative Joints: Salt Water Pool Treatment (Or.)	174	Leake, C. D.—Preanesthetic Drugs (B. M.)	113
Brooks, LeRoy—Mobile Right Colon: Clinical Consequences (Or.)	14	Leef, Edward—Medulloblastoma (C. R.)	42
Brown, Bruce H.—Practice Among the Eskimos (L. M. H.)	259	Lucia, S. P.—The Treatment of Hemorrhagic Disorders (E. C.)	222
Bullock, Lewis T., and Ware, E. Richmond—Pulmonary Embolism (Or.)	79	M	
Bullowa, Jesse G. M.—Pneumonias: Their Management (Or.)	368	Maisler, S., and Barkan, Otto—Adrenalin Chlorid in 1:100 Strength in Ophthalmology (E. C.)	150
Bumpus, H. C., Jr., and Massey, Ben D.—Transurethral Resection: Does It Require as Exactng a Preoperative Preparation as Prostatectomy? (Or.)	89	Massey, Ben D., and Bumpus, H. C., Jr.—Transurethral Resection: Does It Require as Exactng a Preoperative Preparation as Prostatectomy? (Or.)	89
Bumpus, H. C., Jr.—Acute Urinary Infections (E. C.)	366	Mathé, Charles Pierre—Cancer of the Kidney (Or.)	385
Burns, G. Creswell, and Henderson, J. L.—Bromid Intoxication (Or.)	392	Mayer, Harry J.—Multiple Neurofibromatosis (C. R.)	261
Butler, F. O.—Psychosis in the Mentally Defective (Or.)	84	Maynard, Merlin T. R.—Syphilis at the Crossroads (E. C.)	294
C		Meyer, A. W.—The Hunters in Embryology (L. M. H.): Part III	38
Campbell, James V.—Toxemias of Late Pregnancy (Or.)	226	Michael, Paul—The Thymus in Health and Disease (Or.)	101
Cheney, Garnett—A Dengue-Like Fever (Or.)	8	Miller, Hyman: A Rare Book (L. M. H.)	108
Cooke, A. B.—The Physician: Scientist or Artist? (E. C.)	78	Benzedrin Sulphate (E. C.)	295
D		Moody, E. Earl—Constipation in Children (B. M.)	325
Doyle, James C.—Premedication for Surgery (Or.)	248	Morrow, Howard—Venereal Disease Control Program: Department of Public Health, State of California (Or.)	300
E		N	
Escamilla, Roberto F.—Recent Improvements in Methods of Bio-Assay (E. C.)	77	Netzey, Ralph E.—Lead Encephalitis (Or.)	306
F		Newton, Albert H., and Schlappi, Roy F.—Gas-Gangrene Infection of the Uterus (C. R.)	180
Feinberg, Herman—Tests to Determine the Curability of Gonorrheal Urethritis (E. C.)	6	O	
Findlay, H. Verrill—Bladder Irritability Due to Careless Operative Technique (C. R.)	182	Ogden, Eric—Histamin and Epinephrin Tests (E. C.)	7
G		P	
Geiger, J. C., and Gray, J. P.—Influenza: The San Francisco Outbreak of January-February, 1937 (Or.)	379	Palette, Edward M.: Salutation From President Palette (Or.)	217
Ghris, Orrie E.—Sinus Diseases: The Use of Roentgen Ray in Their Diagnoses (Or.)	24	Human Betterment (Or.)	296
Gibbs, Dozier H.—Ureteral Calculi (Or.)	252	Patton, Edwin F.—The Feet in Young Childhood: Some Facts and Fallacies (Or.)	31
Gidoll, Sidney H.—Relationship of Tubinal Enlargement to Septal Irregularities (E. C.)	6	Pearl, Felix—Peripheral Arteries: Their Importance in Industrial Practice (Or.)	35
		Penn, H. S.—Pain Alleviation in Inoperable Malignancy (C. N.)	181
		Peters, Lindsay—Interclocking or Collision of Twins—Dystocia—Low Cesarean Delivery (C. R.)	403

	PAGE		PAGE
Pettit, Albert V.—Pelvic Floor and Adjacent Viscera: Their Plastic Surgery (Or.).....	240	Templeton, H. J.—Dermatitis Venenata (B. M.).....	184
Phillips, Charles Eaton—Surgical Treatment of Stomach Ulcer (Or.).....	169	Thomason, George—Pancreatic Surgery (Or.).....	164
Pottenger, F. M.—Pulmonary Cavity: Optimism Surrounding Its Intelligent Treatment (Or.).....	92	Tillotson, Joseph E.—Pharyngo-Esophageal Diverticulum (C. R.).....	111
Pryor, Helen B.—Constipation in Children (B. M.).....	327	Tucker, George E., and Barnard, Harold Dewey—Expert Medical Testimony in California Courts (Or.).....	95
R			
Redewill, Francis H.—Chronic Prostatitis (B. M.).....	408	U	
Reed, Alfred C.—Clinical Adrenal Insufficiency (Or.).....	308	Ullmann, H. J.—Lymphomatoid Disease: Hodgkins and Leukemic Types—Their Treatment (Or.).....	224
Reeves, James E.—Gonorrheal Tenosynovitis (C. R.).....	112	Updegraff, Howard L.: Reconstruction of the Breast (Or.).....	28
Reilly, William Anthony—Constipation in Children (B. M.).....	328	“Medical Military Preparedness” (E. C.).....	367
S			
Schlappi, Roy F., and Newton, Albert H.—Gas-Gangrene Infection of the Uterus (C. R.).....	180	V	
Shaw, E. B.—The Practice of Pediatrics as a Specialty (Or.).....	372	Van Den Berg, William J.—Acute Metastatic Spinal Epidural Abscess (Or.).....	257
Shephard, John Hunt—Surgical Practice: Looking Forward (Or.).....	377	W	
Seitz, Roland—Convulsions in Children (B. M.).....	44	Ware, E. Richmond, and Bullock, Lewis T.—Pulmonary Embolism (Or.).....	79

GREENS' EYE HOSPITAL

*... for Consultation, Diagnosis,
and Treatment of the Eye*

THE HOSPITAL MAINTAINS

An outpatient eye department which functions daily from 9 a.m. to 6 p.m. A report of findings and recommendations for treatment is returned with patients who are referred for consultation.

An ear, nose and throat department conducted on the same basis as the eye department.

Emergency Eye Service

A twenty-four hour emergency eye service, including Sundays and holidays.

MEMBERSHIP ROSTER : C. M. A.

COUNTY SOCIETIES INDICATED BY KEY NUMBERS

This roster gives the list of members for the year 1936. Deceased members are indicated by *.

KEY NUMBERS FOR COUNTY MEDICAL SOCIETIES

1. Alameda County.
2. Butte County.
3. Contra Costa County.
4. Fresno County.
5. Humboldt County.
6. Imperial County.
7. Kern County.
8. Kings County.
9. Lassen-Plumas-Modoc Counties.
10. Los Angeles County.
11. Marin County.
12. Mendocino-Lake Counties.
13. Merced County.
14. Monterey County.
15. Napa County.
16. Orange County.
17. Placer-El Dorado-Nevada-Sierra Counties.
18. Riverside County.
19. Sacramento County.
20. San Benito County.
21. San Bernardino County.
22. San Diego County.
23. San Francisco County.
24. San Joaquin County.
25. San Luis Obispo County.
26. San Mateo County.
27. Santa Barbara County.
28. Santa Clara County.
29. Santa Cruz County.
30. Shasta County.
31. Siskiyou County.
32. Solano County.
33. Sonoma County.
34. Stanislaus County.
35. Tehama County.
36. Tulare County.
37. Ventura County.
38. Yolo-Colusa-Glenn Counties.
39. Yuba-Sutter Counties.

COUNTY SOCIETY MEMBERSHIP TOTALS

(Year 1936)

Active Members in County Societies

Alameda County	476
Butte County	24
Contra Costa County	49
Fresno County	112
Humboldt County	30
Imperial County	27
Kern County	48
Kings County	15
Lassen-Plumas-Modoc Counties	11
Los Angeles County	2200
Marin County	40
Mendocino-Lake Counties	19
Merced County	28
Monterey County	51
Napa County	34
Orange County	109
Placer-El Dorado-Nevada-Sierra Counties	30
Riverside County	69
Sacramento County	143
San Benito County	7
San Bernardino County	137
San Diego County	258
San Francisco County	812
San Joaquin County	98
San Luis Obispo County	29
San Mateo County	58
Santa Barbara County	102
Santa Clara County	171
Santa Cruz County	30
Shasta County	15
Siskiyou County	15
Solano County	26
Sonoma County	54
Stanislaus County	40
Tehama County	11

Tulare County	38
Ventura County	35
Yolo-Colusa-Glenn Counties	26
Yuba-Sutter Counties	15

Active members	5492
Associate members	6
Retired members	60
Honorary members	9

Total members 5567

Sixty-five members died during the year 1936.

Note.—The California Medical Association by-laws provide for an annual directory. Because every member receives the annual directory of the Board of Medical Examiners of the State of California, and in order to avoid the great cost of duplication of such a directory, the California Medical Association Council has decided to print in the official journal a simple roster of members, giving for each member the city or place of residence, with a key number to indicate the county medical society in which membership is held. For additional information concerning school of graduation, etc., the State Medical Board directory or the central office of the California Medical Association should be consulted. Errors in the list here printed should be promptly reported to the central office of the California Medical Association, Four Fifty Sutter, San Francisco.

In Congestive Heart Failure **Theocalcin**

(theobromine-calcium salicylate)

To diminish dyspnea, reduce edema and increase the efficiency of the heart action, prescribe Theocalcin in doses of 1 to 3 tablets, t. i. d., with meals. It acts as a potent diuretic and myocardial stimulant.

Tablets $7\frac{1}{2}$ grains each,
also Theocalcin powder.

Literature and samples upon request.

BILHUBER-KNOLL CORP. 154 OGDEN AVE., JERSEY CITY, N.J.

CONFIDENCE...

**Lifetime
Baumanometer**
STANDARD FOR BLOODPRESSURE

The weight and bloodpressure readings are recorded with confidence because both instruments operate on the true-gravity principle which assures unvarying accuracy. Smallest, Lightest, Handiest ... the KOMPAK Model, cased in Duralumin, is guaranteed against glass breakage for your Lifetime.

EMMENIN

The orally active, oestrogenic placental
extract elaborated by Dr. J. B. Collip, De-
partment of Biochemistry, McGill University.

(Canadian Medical Association Journal,
February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our
laboratories, we have been able to render
Emmenin entirely free from disagreeable
taste and odor. This has been accomplished
without loss of therapeutic activity, and the
potency is ensured by carefully controlled
biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and stand-
ardized under direct control of the Depart-
ment of Biochemistry, McGill University.

Manufactured by

Ayerst, McKenna & Harrison

Meeting, *First Tuesday.*

Yuba-Sutter County Medical Society
President, Francis P. Wisner, 715 Hart Building, Marysville.
Secretary, Fred W. Didier, Wheatland.
Meeting, *Second Tuesday.*

Emulsification

AIDS Utilization

It is commonly believed that emulsification affects utilization. The minute emulsification of Maltine and cod liver oil, made possible by the exclusive Maltine process, is believed to be largely responsible for the thorough utilization of food values contained in MALTINE WITH COD LIVER OIL. In fact, laboratory tests on animals indicate that the vitamin A value of cod liver oil is enhanced *twofold* when emulsified in Maltine, as in MALTINE WITH COD LIVER OIL. A microscopic study of MALTINE WITH COD LIVER OIL reveals exceptionally small globules of uniform size and distribution, whereas the same study of other widely marketed products shows bulky globules of uneven size and distribution. MALTINE WITH COD LIVER OIL is made entirely

in the Maltine laboratories with specially designed vacuum equipment.

MALTINE WITH COD LIVER OIL is guaranteed to contain vitamins A, B, D and G. Does not contain molasses or added syrups. The Maltine Co., 60 Hudson St., New York.

GENUINE
Maltine

Trade-Mark Reg. U. S. Pat. Off.

CO-OPERATE WITH YOUR ADVERTISERS

CALIFORNIA AND WESTERN MEDICINE, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention CALIFORNIA AND WESTERN MEDICINE.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this JOURNAL to members and readers.

A SERVICE AGENCY—FOR READERS

THE JOURNAL of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely free to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in CALIFORNIA AND WESTERN MEDICINE, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. CALIFORNIA AND WESTERN MEDICINE and the A. M. A. Service Bureau desire to serve you.

THE CONTINUOUS COURSE IN OPERATIVE SURGERY

Will Start January 5, 1937

DESIGNED FOR PHYSICIANS IN SAN FRANCISCO AND VICINITY

SUBJECTS INCLUDED:

Stomach and duodenum. Colon and rectum. Gall-bladder and bile ducts. Small intestines.

METHOD OF STUDY:

All of the above topics will be considered in the same manner. The descriptive and surgical anatomy of the organ in question will first be gone over, in the form of lectures, demonstrations on the cadavers, and dissections by the students themselves. The pathology, diagnosis and treatment of each subject will then be briefly considered, and particular attention given to the latest and most approved methods. The principal operations will be described by the instructor and performed by the students themselves on cadavers and fresh human material. Only the best and most up-to-date technique will be included and the students will be required to practice the work until they have not only mastered the subject but have developed the proper amount of skill and speed.

TIME REQUIRED AND FEE:

The work will be given every Tuesday from 11 a.m. to 2:30 p.m. Those desiring to spend additional time may do so without extra charge. Students taking the course will have the privilege of witnessing operations, with demonstrations, on the living at various times during the week. The fee will be \$15 per month.

Applicants must be graduates of schools approved by the State Board of Medical Examiners

For descriptive circular and further information inquire of

SAN FRANCISCO POLYCLINIC AND POSTGRADUATE COLLEGE

New Orleans, La.

Till taught by pain

Men really know not what good water's worth.
If you had been in Turkey or in Spain,
Or with a famished boat's crew had your berth,
Or in the desert heard the camel's bell,
You'd wish yourself where truth is—in a well.

—Byron

Every man will have his own criterion in forming his judgment of others. I depend very much on the effect of affliction. I consider how a man comes out of the furnace; gold will lie for a month in the furnace without losing a grain.—Richard Cecil.

The secret of happiness is not in doing what one likes, but in liking what one has to do.—James M. Barrie.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE

(In affiliation with Cook County Hospital)

Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses.

SURGERY—General Course, One, Two, Three and Six Months; Intensive Course, Surgical Technique, every two weeks; Special Courses.

NUTRI-AD ARTHROPHYLL

(6)

A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » » »

NUTRI-AD—ARTHROPHYLL(6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL(6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

Benzedrine Sulfate in Mood and Fatigue.—Myerson (Arch. Neur. and Psych., 30:816, October, 1936), suggests the use of Benzedrine Sulfate (benzyl methyl carbinamine sulfate S. K. F.) to alleviate certain types of fatigue and depression.

When administered to normals suffering from fatigue and slight malaise due to insufficient rest or sleep, immediate benefit and relief of a pleasant type were experienced. To obtain this result 10 milligrams upon arising was usually sufficient. The effect lasted two hours or more. A dose of 30 milligrams was apt to produce restlessness and overexcitability; and sleeplessness at night followed administration in the late afternoon. No ill effects and no signs of craving were noted in any of the patients.

American Medical Association Council Seals.—If they could talk, Council Seals would say: "When you see one of us on a package of medicine or food, it means first of all that the manufacturer thought enough of the product to be willing to have it and his claims carefully examined by a board of critical, unbiased experts. . . . We are glad to tell you that this product was examined, that the manufacturer was willing to listen to criticisms and suggestions the Council made, that he signified his willingness to restrict his advertising claims to *proved* ones, and that he will keep the Council informed of any intended changes in product or claims. . . . There may be other similar products as good as this one, but when you see us on a package, *you know*. Why guess, or why take someone's self-interested word? If the product is everything the manufacturer claims, why should he hesitate to submit it to the Council for acceptance?"

The sublime and the ridiculous are often so nearly related that it is difficult to class them separately. One step above the sublime makes the ridiculous and one step above the ridiculous makes the sublime again.—Thomas Paine.

Cardiovascular Disease. By Joseph H. Schrup, M. D., Dubuque, Iowa. Paper. Pp. 20. Price, 12 cents. Dubuque, Iowa: J. H. Schrup, 1936.

Plastic Surgery of the Nose. By J. Eastman Sheehan, New York. Second Edition, entirely rewritten. Cloth. Pp. 186, with 131 text illustrations, including seven in color, and fourteen full-page plates, consisting of 104 photographs. Price, \$9. New York: Paul B. Hoeber, Inc., 1936.

BOOK REVIEWS

A Dissertation on the Sensible and Irritable Parts of Animals. By Albrecht Von Haller (1708-1777). Price, \$1. Johns Hopkins Press.

This is a reprint of the memoir read by Von Haller at Göttingen in 1752.

The Practice of Medicine. By Jonathan C. Meakins, M. D., LL. D., Professor of Medicine, McGill University. Pp. 1343. Cloth. C. V. Mosby Company, St. Louis.

Meakins frankly admits that he has written this treatise on the practice of medicine for the student and the general practitioner. As a feature he has given symptoms particular prominence, claiming that they give the clues to diagnosis and the solution of clinical riddles. Another feature is the use of many illustrations, 540 of them, for the purpose of amplifying the text and imparting more informative facts.

In other respects the subject has been covered exceedingly well and with evident thoroughness. Many references are included.

HEALTH AND ACCIDENT INSURANCE

OMAHA, NEBRASKA

\$200,000 deposited with State of Nebraska, for our members' protection.

This treatise will be appreciated by the undergraduate and the younger practitioner, as it will lead them to acquire more complete knowledge.

Plastic Surgery of the Nose. By J. Eastman Sheehan, M. D. Second Edition. Pp. 186. Price, \$9. Paul B. Hoeber, Inc.

This is an ordinary text that sets forth what plastic surgery may do for a deformed or injured nose. The descriptive text and illustrations are largely generalizations. Detailed technique is wanting.

A Textbook of Medicine. By Charles P. Emerson, M. D., Professor of Medicine, Indiana University. Cloth. Pp. 1296. Price, \$8. J. B. Lippincott Company.

This well-known and highly regarded clinician was provided the opportunity of writing this text by reason of his appointment as research professor of medicine of the Indiana University.

The author cites four features that characterize this text: Clinical pictures of disease, biographical notes of men concerned with historical advances in medical knowledge, diseases are presented as defensive syndromes, the patient's emotional reactions, and environments.

It is a well-written text and ably presents the subjects discussed. It is a dependable text for students.

The Physiology and Pharmacology of the Pituitary Body. By H. B. Van Dyke, Professor of Pharmacology, Peiping Union Medical College. Cloth. Pp. 554. Price, \$4.50. University of Chicago Press.

This book represents an attempt to describe and evaluate our knowledge of the pituitary body in terms of physiology and pharmacology. It is not possible to state that what we know in regard to the pituitary and its functions is complete. This complex body and its hormones still holds much of mystery, hence studies and deductions such as this are received as mere progress records.

(Continued on Page 17)

Pneumonia is an emergency!

ANTIPNEUMOCOCCIC SERA *Lederle*

THESE are essential facts in the serum treatment of pneumonia—

Serum must be specific for the type of pneumococcus causing the infection.

The earlier the serum is used, the lower the death rate.

Serum treatment should be both *prompt* and *intensive*. The dosages recommended are intended to be administered within a 12-24 hour period. Antipneumococcic serum therapy is less effective when the basic dosage is spread over several days.

The death rate rises rapidly with the lapse of time from the onset of the disease to the beginning of adequate serum therapy, and the amount of serum necessary for adequate treatment increases as the disease progresses.

Cecil* has combined the reports of several authors, which demonstrate the importance of early administration:—

Type	First 4 Days		After the Fourth Day		Controls (all days)	
	Cases	Mort. %	Cases	Mort. %	Cases	Mort. %
I	744	9.6	641	23.6	565	33.6
II	362	29.6	155	38.7	516	45.3

After the fifth day in the non-bacteremic cases and the fourth day in bacteremic cases, enormous amounts of serum are needed—and the prognosis may be poor. Early and adequate therapy saves lives—and serum.

*Dr. Russell Cecil, N. Y. S. Jour. of Medicine, Vol. 35, Nov. 15, 1935, No. 22, p. 7.

Building for the FUTURE on FOUNDATIONS of the PAST

FOR over one-half century, THE JAMES H. BARRY COMPANY has adhered only to the highest ideals in the conduct of its business. This is a policy which has proved itself reciprocal and to which we attribute in a large measure the forward strides of this company, year after year. Buyers of printed matter have approved it by their constancy of patronage and by commending us to their friends.

« « All of which means simply this: That we have gathered about us a sincere and conscientious group of men and women who are actively and entirely occupied with but three thoughts—the thoughts of QUALITY, SERVICE and VALUE in the sale and manufacture of the printed piece.

« « If you are not certain of these three attributes before placing your next printing order, we invite you to visit one of the most modern printing plants on the Pacific Coast, meet our organization, and let us prove to you how profitable the blending of your ideals and ours will be.

BOOK REVIEWS

(Continued from Page 14)

Bibliography is presented in 188 pages of the text. The remainder records some of our accepted physiologic and pharmacologic findings in compilation form. As such it serves as a satisfactory reference guide.

International Clinics. Vol. IV, Forty-Sixth Series. 1936. J. B. Lippincott Company.

Nineteen contributors present the articles in this volume devoted to medicine and recent progress in dermatology. The established standard of this series is maintained.

A Health Education Workbook. By Kathleen W. Wooten, Professor of Health and Physical Education, Georgia State College for Women. Paper. Pp. 273. Price, \$1.50. New York: A. S. Barnes & Co.

This workbook is an activity program and outline for the practical training of teachers, social workers, nurses, and parents. As such it will do much to encourage the practical and abolish the fads in school or community health programs.

Diseases of the Coronary Arteries and Cardiac Pain. Edited by Robert L. Levy, M. D., Columbia University. Cloth. Pp. 445. Price, \$6. The Macmillan Company.

This clinic on coronary arteries is conducted by fourteen writers. Since 1912, when Herrick directed attention to the coronary arteries, much interest and increasing attention has been given this subject. Great advances in knowledge have been made and opinions are becoming crystallized. We welcome this presentation of our present knowledge of the subject and summary of clinical experiences. The tragedy of the coronaries has cut short the careers of distinguished men in their height of usefulness. Compelling attention has been directed to these cardiac vessels, and as a result there has been a rapid accumulation of information on the subject. This text takes stock of that information and indicates the direction in which future studies of the subject should be made. It is a well-done compilation.

Herrick, Cohn, and Wiggers, in an advisory editorial capacity, insure the dependability of the text. Authorization is further insured by the collaboration and writings of Beck, Blumgart, Dublin, Kerr, Smith, Wearn, White, Wilson, and other acknowledged clinicians.

Each chapter is so well done that it is impossible to point to an outstanding chapter—the entire book is outstanding.

Suffice it, then, to state that no practitioner or specialist can afford to neglect obtaining this book, or to diligently read and study it. Doing so will enable the individual to acquire a true knowledge as to what is known today about coronary disease.

Skin Diseases in Children. By George M. MacKee, M. D., Columbia University, and Anthony C. Cipollaro, M. D., Columbia University. 153 illustrations. Cloth. Pp. 333. Price, \$5.50. New York: Paul B. Hoeber, Inc.

These joint authors have written a text that should be very helpful to the general practitioners. It is practical, with omission of pathological description, disputed points,

THE BEST TEST IS THE CLINICAL RESPONSE

Here is an opportunity to prove that endotoxic infections respond rapidly when treated with

EDWENIL

the polyvalent, protein-free, antibacterial agent. The salient points are these:

- (1) The promptness of the response; the defenses are aroused immediately, resulting in a "shower of antibodies."
- (2) There are no detrimental "reactions" nor unpleasant anaphylactic phenomena.

Edwenil is indicated in all endotoxic bacterial invasions—**respiratory infections, such as pneumonia, influenza, and colds;** septic conditions, such as abscesses, boils, and carbuncles; acute specific fevers, such as whooping cough and measles.

TWENTY-FIVE YEARS AGO

(Continued from Preceding Page)

remedy, is abused nowadays by some journals is enough to bring tears to the eyes of any self-respecting crocodile! Were we but crocodiles we would weep most copiously (with apologies to Chimmie Fadden). All of which is but a painful part of the turgid feelings aroused by reading a circular from the "Dioradin Company," addressed "To the Physicians of California," and subheaded "Dr. Max Rothchild's Disgraceful Editorial." . . .

Salvarsan—A Warning.— . . . The important point is this: A good, sensible view of salvarsan should be taken by the physician. It should be considered preëminently as a symptomatic treatment and a marvelous one, and not as a cure-all. Let us not dispense with the time-honored remedies, which are so necessary and which so frequently act far better after the use of the arsenic.

Medical Defense.—No criticism of the practices of liability insurance companies has been uttered by the State Society or voiced by the Journal at any time since we, as a society, undertook the coöperative defense of our members in alleged malpractice suits. Some of them are mightily open to criticism, however. (In passing let it be noted that the defense has won every suit defended by the State Society since the work began.) . . .

Public Health and Its Foes.—The introduction into Congress of a bill by Senator Owen to create a department of public health, a few years ago, aroused immediate opposition from certain questionable sources. The same interests which had opposed the Pure Food and Drugs Act, opposed this bill; and probably for similar reasons. But this time they were more open in their opposition. They organized what they were pleased to call the "League for Medical Freedom," made a loud cry about

the "doctors' trust" and assailed the medical profession and the American Medical Association. . . .

The Los Angeles County Medical Association quite naturally resented the reflections cast upon those physicians in Los Angeles (Senator Works' home) who had attended him, and wrote to the Senator on the subject. Considerable correspondence resulted, and all of this, together with a valuable mass of related material, has been published in Bulletin No. 22 of the Los Angeles County Medical Association. We understand from the secretary, Dr. George H. Kress of Los Angeles, that a copy of this Bulletin has been sent to every physician in the State. If you have not received one, or if you desire others, you can secure copies from Doctor Kress. It is unfortunate that the matter contained in this little document cannot be placed in the hands of laymen, for it is the ordinary citizen who is to settle this question in the end. . . .

From an article on "Report of a Case of Polycythemia" by William C. Voorsanger, M. D., San Francisco.

Polycythemia was first described in 1892 by Rendu and Widal, with two salient features:

1. Chronic cyanosis due to polycythemia.
2. Splenic enlargement.

These authors attributed this symptom complex to a splenic tuberculosis. Vaquez in 1899, Turk in 1902, and Osler in 1903, called general attention to the above syndrome, demonstrating that it was not due to splenic tuberculosis, but to a primary hyperplasia of the erythroblastic bone marrow. . . .

From an article on "Analysis of Treatment of Sixty-Two Cases of Syphilis with Salvarsan" by Louis Gross, M. D., and Walter S. Johnson, M. D., San Francisco.

When salvarsan was ushered into syphilitic therapeutics, it was heralded as a great cure-all, assuming a responsibility no other drug ever had to contend with. The fact

(Continued on Page 22)

CONSERVATION OF ESSENTIAL ELEMENTS IN PROTECTIVE FOODS

I. MINERALS

● Considerable differences may exist between the mineral contents of foods from both the qualitative and quantitative standpoints. In fact, variation in mineral content has been noted even in the same plant variety; such variations being dependent, among other factors, upon soil or climatic conditions (1).

A striking example of the influence of one of these factors is the relative richness in iodine of field crops raised in certain coastal regions of this country where the soil is also high in iodine.

From the point of view of those concerned with human nutrition, interest in the mineral content of the food supply is usually centered around calcium, iron and iodine; since it is generally agreed that of all the essential minerals, these are the ones most apt to be inadequately supplied by the average varied diet. Conservation of these minerals in foods is, therefore, a matter of considerable practical interest.

Unlike the vitamins, minerals are not lost during storage of fruits and vegetables. However, solution losses during cooking may be severe, due to the fact that most minerals, as they occur in the plant, are soluble, or at least are extractable, by the water in which they are cooked. For example, cabbage cooked by the usual home method has been shown to lose from 21 to

72 per cent of its calcium (2).

As exemplified by these studies, solution losses of minerals in leafy vegetables are usually high. Losses in vegetables as a class are not, however, so excessive, as indicated by an average reported loss of 19.5 per cent of the calcium in seven common vegetables (3).

The average decrease during cooking in the ash content of five common vegetables has been found to approximate 37 per cent (4).

While the extent of mineral loss during ordinary home cooking methods will vary with the particular element under consideration as well as the food in which it is contained, sufficient evidence is at hand to indicate that such losses may be considerable. It is further apparent that discarding the cooking water—the usual home practice—entails a loss of valuable, essential mineral components of food.

Modern practice in commercial canning goes far in preventing these solution losses of minerals. Canned foods are cooked by the heat process accorded them while still contained within the hermetically sealed can. A minimum of water is used which also remains within the can, conserving for the consumer's use those extractable essential mineral elements which may be lost to the cooking water during home preparation of market varieties of foods.

Diabetics

live longer today

THE LIFE SPAN of the diabetic has been lengthened considerably following the discovery of Insulin and the growing knowledge of its use. There is, however, a definite responsibility on the part of the physician to educate the many new diabetics in the importance of proper diet and proper use of Insulin.

The apparent increase in diabetes in recent years has been attributed to the modern manner of living, increased sugar consumption, overeating and lack of muscular exercise. With proper management the great majority of these patients can be kept well-

nourished, sugar-free and at work.

When Insulin therapy becomes necessary, Insulin Squibb may well be a product of choice. Insulin Squibb is highly purified, highly stable and remarkably free from proteinous, reaction-producing substances. Great care is taken in its assay to make it uniformly potent. More physicians and more patients are using Insulin Squibb than ever before. They rely upon the quality and dependability of this Squibb Product.

Insulin Squibb of the usual strengths is supplied in 5-cc. and 10-cc. vials.

INSULIN SQUIBB

A SQUIBB GLANDULAR PRODUCT

Mary Lou had rickets when she was a baby. Once that might have made her easy to identify! But now doctors know how to treat rickets effectively, and they know what to do to prevent it. Promptly treated, rickets seldom results in bow legs or knock knees. So the answer to our puzzle is—you can't pick out Mary Lou!

Fewer children with iron braces! More children with legs as straight and handsome as young saplings! Fewer hollow chests! More well-shaped jaws and pleasing little profiles! *These are some of the advantages which modern developments in vitamin medication—especially vitamins A and D—have made possible.*

Here is something we'd like to have you keep in mind: Problems involving vitamins

have been studied in the Parke-Davis Laboratories every day for over twenty years—a rich background of experience. For your young patients or old, it is a sensible precaution to specify "Parke-Davis."

Parke-Davis Haliver Oil with Viosterol is supplied in 5-cc. and 50-cc. vials with dropper, and in boxes of 25, 50, 100, and 250 three-minim capsules.

Haliver Oil is the *original* halibut liver oil preparation introduced to the medical profession in February, 1932.

TWENTY-FIVE YEARS AGO

(Continued from Page 18)

that it has withstood for almost a year all onslaughts, proclaims it as a wonderful preparation.

In this series of sixty-two cases we have aimed to place our material before you in a clear and concise manner. We have controlled our cases with Wassermann tests, and in over half of the cases with Noguchi also. . . .

From an article on "Multiple Papillomata of the Larynx in Children—Report of Two Cases," by E. C. Sewall, M.D., San Francisco.

I wish to report two cases which have come under my care in the past few years, first because of their comparative rarity and, second, because of the ease with which the latter case was handled as compared with the former due to the improvement in technique which a very short time has brought to our aid. . . .

From an article on "Hospital Department—San Francisco Hospitals," by William R. Dorr, M.D., San Francisco.

Perhaps no other city in history, and certainly no other modern city, has had more incentive to construct and put in running order a large number of hospitals than San Francisco has had during the last five years, and I am sure that no community could have responded more loyally to the need than has been done during this more or less trying period.

In the spring of 1906 San Francisco had about forty hospitals, of which very few could be described as thoroughly modern and up to date. . . . After the great conflagration only four hospitals remained that were housed in modern buildings built for hospital purposes and few of the old structures remained, so that hospital authorities

were pushed to the utmost to provide temporary makeshifts to fill the need for hospital treatment.

It was not long, however, before plans were being adequately made to fill the need, so that today we have a large number of hospitals, all of which are modern and up to date in every way, that have been built for hospital purposes and have all been completed or started during the last five years. . . .

From an article on "Selected Chapters in the Study of Speech Disturbances, No. 2—The Responsibility of the General Practitioner to the Child with a Speech Defect, with Suggestions as to Prophylactics," by Henry Horn, M.D., San Francisco.

It is beginning to be believed that the day of the general practitioner is departing and that the specialist is usurping the throne of the old family physician. No better refutation of this fact is needed than to observe the rapacious appetite of the general practitioner for special knowledge. It is the specialist who is being forced back into the ranks of the generalist by the tremendous border-line studies that are having a vast influence on his own narrow specialty. . . .

From an article on "Mechanical Efficiency" by James T. Watkins, M.D., San Francisco.

The purpose of the group of lectures, of which this is one, is to give you some insight into the art or, as it is fast becoming, the science of right living; right living especially as it applies to yourselves and to your charges. In my own lecture I shall briefly direct your attention, first, to what we have come to regard as the state of maximum efficiency of the human body. I shall then dwell upon conditions which are essential to this state of well-being. Finally, I shall discuss some of the commoner causes of physical inefficiency. Such a study is peculiarly the function of that branch of the healing art called orthopedic surgery. . . .

The "Prevention of Sexual Diseases." By Victor C. Vecki, M. D., with introduction by William J. Robinson, M. D., 12 Mount Morris Park W., New York, 1910.

The synoptical plan followed by the author in the little work before us detracts in nowise from the frank and wholesome breeziness of his treatment of the subject-matter. He has condensed in most cogent and interesting form practically the substance of the most mature views on this vital and hitherto usually glossed-over phase of social life. No attempt has been made to benumb the mind with a mass of indigestible statistics; or make mawkish appeal to the sensibilities through the recital of harrowing case histories. The time and the opportunity for the dissemination of wholesome and unglossed truths regarding the consequences of the disobedience of the laws of sex hygiene have long awaited fearless propagandists. The author is one of the first to come into the open with commendable directness and vigor. . . .

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 69)

Five members of the ring are fugitives, and bench warrants were issued for them several weeks ago." (San Francisco Chronicle, November 24, 1936.)

"Five members of a coast-wide illegal operations ring yesterday were given suspended sentences and placed on five years' probation by Superior Judge Arthur Crum. Violet Pelligrini, a nurse, was sentenced to one year in the county jail as a part of her probation. Lillian Wilson and Grace Moore, receptionists, were ordered to spend six months of their probation period in the county jail. J. C. Shinn and John Creeth, clerks in the office of the Medical Acceptance Corporation, were placed on probation without jail terms." (Los Angeles Examiner, November 17, 1936.)

"Only Mexican citizens will be allowed to practice medicine, law, dentistry or other professions in the southern republic if proposed legislation is adopted, the Associated Press reported yesterday from Mexico, D. F. Statutes are being prepared, the report stated, to require all professional people in Mexico to take out naturalization papers. This probably would end the practice of San Diego physicians and dentists, who are frequently called to Tijuana, Mexicali, and Ensenada to attend clinics and perform operations, Louis Castro, Mexican Consul here, said. . . ." (San Diego Union, November 8, 1936.) Note: A letter recently received from a Japanese physician licensed in this State, now visiting in Japan, related that similar regulations are in force in Japan.

"Conviction of two Los Angeles physicians on charges of illegal sale of morphin was upheld yesterday by the United States Circuit Court of Appeals, sitting at San Francisco. The doctors, F. T. Cary and E. H. Williams, were sentenced December 3, 1934. This means that Doctor Cary will have to serve a year in a road camp. Doctor Williams was placed on two years' probation. 'This is the first decision of its kind on the Pacific Coast and is expected to have far-reaching results,' it was announced last night by Assistant U. S. Attorney Jack Irwin, one of the prosecuting attorneys. 'In the past it has been possible for persons to delay the execution of their sentences indefinitely. A ruling of the United States Supreme Court in September, 1934, is now in effect, expediting criminal appeals and eliminating delays.' Doctor Williams and Doctor Carey were convicted on charges of conspiracy to issue narcotic prescriptions unlawfully. Doctor Williams had served without salary as a member of the city narcotic staff for many years." (Los Angeles Illustrated Daily News, November 17, 1936.)

"E. B. Hartman, former San Bernardino chiropractor, is making a final move to avoid serving 180 days in the

county jail by filing a petition for a writ of habeas corpus with the State Supreme Court at San Francisco, it was learned today. Hartman was convicted on two charges of violating the State Medical Act and sentenced by Justice Russell A. Wickizer to serve 180 days on one count and ninety days on the other, the terms to run concurrently. . . . Hartman was convicted of practicing medicine without a State license and unlawful use of the prefix 'Dr.' His chiropractor's license was revoked after his conviction." (Ontario Report, November 27, 1936.)

"Accused of performing an illegal operation that resulted in a white girl's death, Dr. Jack Smitherman, forty-seven, negro, 215 East Forty-fifth Street, was arrested yesterday on suspicion of murder and suspicion of performing the operation. Virginia Sandefur, twenty-one, died in Huntington Park Hospital allegedly as the result of an operation the negro physician performed." (Los Angeles Daily News, December 7, 1936.)

"With his bond reduced from \$50,000 to \$5,000, Dr. Jack Smitherman, negro physician charged with malpractice which assertedly resulted in the recent death of a white woman, Mrs. Virginia Sandefur, yesterday gained his release from the county jail. He is to appear December 21 for preliminary hearing before Municipal Judge Benjamin J. Scheinman." (Los Angeles Examiner, December 15, 1936.)

"At the request of the District Attorney's office, charges of murder and malpractice against Dr. Jack Smitherman, negro, yesterday were dismissed by Municipal Judge Benjamin J. Scheinman. . . ." (Los Angeles Examiner, December 17, 1936.)

"Pleading guilty to a charge of selling useless medicine under a violation of the California Pure Drug Act, Dr.

James Decker, osteopath, of 5729 Shafter Avenue, was sentenced to \$25 fine and 180 days' probation yesterday by Police Judge Chris Fox in Oakland. He was arrested by C. B. Heizer, inspector for the State Department of Public Health." (San Francisco Examiner, East Bay Edition, December 16, 1936.)

"A murder charge against Mrs. Regina Holscher, fifty-eight, of 3425 Larissa Drive, was ordered dismissed today by Superior Judge Fricke after the woman pleaded guilty to having performed an illegal operation on Mrs. Hazel Scott, forty-one, of 4129 Tujunga Street, Burbank, who died last August 28 at General Hospital. Mrs. Scott's death was listed in the hospital records as having been caused by pneumonia. The coroner's office report said the operation was a contributing cause of death. Mrs. Holscher applied for probation on the operation charge, and Judge Fricke set December 18 as the date for the hearing of the motion." (Los Angeles Herald-Express, December 3, 1936.)

"Sixty days in the city jail was prescribed yesterday in Municipal Court for Alex F. Pena, on the charge that Pena illegally posed as a doctor. Pena already was an inmate of the jail, following his plea of guilty to a charge of petty theft from Lupe Castellon. She charged she went to his Main Street offices for a treatment and that when she gave him \$10 he went out to change the bill and never returned. 'If you have got it, I can cure it,' the business card bearing 'Dr.' Pena's name stated, the Court was told. The card recently came into the hands of John R. Ronan, investigator for the State Board of Medical Examiners." (Los Angeles Examiner, December 9, 1936.)

"Dr. George W. O'Donnell of San Francisco, whose license to practice medicine in California was revoked last October by the State Board of Medical Examiners, yesterday filed a petition in the Superior Court for a writ of

(Continued on Page 26)

Old Way...

CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.

*Frazer, J. G.: *The Golden Bough*, vol. 1, New York, Macmillan & Co., 1928

It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

New Way...

Preventing and Curing Rickets with OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a natural vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets,

regardless of degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

Mead's Oleum Percomorphum is not advertised to the public and is now obtainable at drug stores at a new economical price in 10 c.c. and 50 c.c. bottles and 10-drop capsules.

review. The petitioner contends there was no evidence offered at the hearing before the State Board to bear out the Board members' contention he performed an illegal operation upon Mrs. Blanche LaBerta Miller of San Francisco. Doctor O'Donnell denies performing the operation, declaring that he merely prescribed normal medical treatment for the woman." (Sacramento *Bee*, November 10, 1936.)

"Bench warrants for five persons allegedly connected with the state-wide abortion ring, were issued yesterday by Superior Judge George Steiger. The five named in the bench warrants were: Dr. H. L. Houston, Mrs. Ruth Hanson, Viola Warner, Bess McCarthy, and Beatrice Bole. . . ." (San Francisco *Examiner*, November 24, 1936.)

"City Attorney Claude Rowe informed the City Commission by letter today, through Finance Commissioner William Glass, that osteopaths and chiropractors are not

entitled under the city ordinance to obtain emblems for their automobiles which entitle the owner of the car to certain police privileges. Rowe said the emblem can be given only to physicians and surgeons licensed under the State Board of Medical Examiners. The Commission gave the osteopaths and chiropractors a week to answer before taking action." (Fresno *Bee and Republican*, November 27, 1936.)

Recent correspondence with H. F. Hudson, attorney-at-law, Wichita, Kansas, indicates he has brought legal action on behalf of a client against one Thomas J. Libbin, Los Angeles, who, Attorney Hudson claims, calls himself a psycho-analyst. No such individual is licensed to practice any system of the healing art in the State of California. Mr. Hudson claims that during the period April 18, 1928 to June 2, 1932, his client (then a resident of Los Angeles) paid Libbin \$7,332.50, "mostly at the rate of \$10 per hour. In addition, he also got two notes out of her for the sum of \$1,000. Instead of being satisfied with the \$7,332.50, he had the gall to sue her on the notes and when he did I slapped a counterclaim on him, in which I seek to get a judgment of \$7,332.50 and cancel

came into the picture. He allegedly got an order signed by the dying Baker, authorizing him to withdraw the money from the bank. It is charged that Farrell paid Doctor Housman \$6,100 for his alleged services; however, two noted brain specialists were called into the case and were paid only \$600. This latter charge is not disputed. Farrell also is charged with having paid Attorney Taaffe and Harris a 'legal fee' of \$1,250 out of Baker's money. According to Mrs. Baker, \$1,394.60 of the original \$9,874.14 was spent legitimately on funeral expenses and hospital costs. She demands return of \$8,479.54, plus cost of suit, including \$2,500 attorneys' fees. Russell Sweet, football coach at San Francisco Junior College, recently sued Frank Baker, alleged driver of the car that struck his machine, killing his wife, for \$75,000 for her death and \$25,000 for his own injuries." (San Francisco Call-Bulletin, December 1, 1936.)

The records of the Board of Medical Examiners show recent correspondence regarding an individual known as Clyde E. Tillotson, who, according to reports, was formerly employed by the Federal Government as a physician in a C. C. C. camp near Fresno. On October 1 he was reported as held in the San Diego county jail, and his picture, forwarded by San Diego County Sheriff, shows him to be No. 55093, held, we understand, on a charge of impersonating a federal officer. Report also relates that a complaint has been filed and a warrant issued charging him with violation of the Medical Practice Act. According to the Federal Bureau of Investigation, J. E. Hoover, Director, Washington, D. C., Clyde Tillotson has been involved in legal difficulties in Des Moines, Iowa (bigamy); Ottumwa, Iowa (bad check); San Diego, No. 11186 (August 27, 1936, drunk, impersonating federal officer); San Diego, No. 55093, August 31, 1936, "Section 76, Title 18, U. S. C." Headquarters, Fresno District, Civilian

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

**Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack
and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.**

Zera E. Bolin, M.D., 490 Post Street, San Francisco, California. ✓ ✓ ✓

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

Mailing containers sent on request. Special delivery postage insures prompt, accurate service.

Tried, tested and proven for three years before offered to the medical profession for general use. Now in wide use in almost every state in the Union as well as several foreign countries. Phone or write today for descriptive literature or a free demonstration of the KING THERMANESTER!

Conservation Corps, on September 14 related that "Doctor Tillotson was engaged as a contract surgeon in this district on January 18, 1936. . . . The diagnoses of medical and dental cases transferred for treatment to the Fresno District Dispensary by Doctor Tillotson were erroneous, except in one instance. . . . Doctor Tillotson was relieved on June 30, 1936, because of the above continued deficiencies."

"The most contemptible of all rackets are those whose victims are the aged and sick; hence it is most welcome news that the Federal Government has stepped into the fake eyeglass and medical racket and put seventeen of its leading fakers under arrest. These men went around the country selling dime-store eyeglasses for prices up to \$100 or more. Then a follow-up man would come in, assure the unfortunate dupe that he or she needed an immediate 'operation' to correct the trouble produced by the glasses and get from \$500 to \$1,000 for a fake operation. These

miscreants, of course, should be jailed for as long a time as the law allows. That, however, will not put an end to such racketeering. People must learn, when they suffer from physical ailments, to consult only qualified, licensed and reputable physicians, dentists, optometrists, etc., who have permanent residences and place of business and, therefore, are responsible. If everyone would adhere to that simple and wholly reasonable principle of action, the quack and the medical racketeer automatically would go out of business." (Editorial, *Sacramento Bee*, October 12, 1936.)

Report from the Southern Investigation Department relates that Clifford Pickett on November 24, 1936, pleaded guilty in the courts of Los Angeles to a charge of violation of the Medical Practice Act and on December 1 was sentenced to serve 180 days in the city jail, sentence being suspended and defendant placed on probation for two years.

Behind MERCUROCHROME

(dibrom-oxymercuri-fluorescein-sodium)

is a background of

Precise manufacturing methods insuring uniformity

Controlled laboratory investigation

Chemical and biological control of each lot produced

Extensive clinical application

Thirteen years' acceptance by the Council of Pharmacy and Chemistry of the American Medical Association

A booklet summarizing the important reports on Mercurochrome and describing its various uses will be sent to physicians on request.

minimizes scarring

A FEATURE OF

ANTI-PYREXOL

This most comfortable, and least troublesome dressing for burns may be depended upon to:

1. Relieve pain promptly.
2. Protect denuded areas.
3. Give antiseptic protection.
4. Combat toxemia.
5. Promote prompt healing.
6. Minimize scarring.

Anti-Pyrexol is available through surgical supply houses and drug jobbers in 2-oz. tubes, 1-lb., 5-lb., 10-lb. tins. For technical information address Mona E. Bettin (M.D.), Pathological Laboratories, Roosevelt Building, Los Angeles, or:

Bequest Forms: Unto the California Medical Association*

FORM OF CLAUSE OF WILL PROVIDING FOR CASH BEQUEST

I hereby give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California, the sum of \$_____ to be known as the _____ Gift, to be used and expended by said corporation for scientific, educational, or hospital purposes.

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR CASH BEQUEST

I give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California, the sum of \$_____, to be held as a fund, to be known as the [here insert name desired] Fund, the principal whereof shall from time to time be invested to the best advantage compatible with safety, and the income whereof shall be used and applied for scientific, educational, or hospital purposes.

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR BEQUEST OF PERSONAL PROPERTY

I give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California [here describe the property], the same, or the proceeds thereof, to be held as a perpetual fund, to be known as the [here insert name desired] Fund, the income whereof shall be used and applied for scientific, educational, or hospital purposes. The said corporation shall have the power to sell said property and to invest and reimburse the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California, to aid and further its scientific, educational, and hospital purposes, and to be known as the _____ Gift, the following described real property situate in the County of _____, State of California, and more particularly described as follows, to wit:

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California [here describe the property], the same, or the proceeds thereof, to be held as a perpetual fund, to be known as the [here insert name desired] Fund, the income whereof shall be used for and applied to the support and maintenance of scientific, educational, or hospital purposes. The said corporation shall have the power to sell said property and to invest and reinvest the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

Bovine Tuberculosis.—Still true is the statement that there are more tuberculous cattle in California than in any other state. Due to the efforts of the State Department of Agriculture and the health workers of the State, progress is being made in the eradication of this disease. Imperial County is now included in the nine counties having a herd infection of less than 0.5 per cent.

The present status of the eradication control areas in California is:

Counties	Cattle Infected
9.....	Less than 0.5 per cent
5.....	Less than 1 per cent
32.....	From 1 to 3 per cent, inclusive
3.....	From 4 to 7 per cent, inclusive
5.....	From 8 to 15 per cent, inclusive
4.....	Over 15 per cent

* These Bequest Forms were discussed editorially in CALIFORNIA AND WESTERN MEDICINE, for March, 1936, p. 145, and June, 1936, p. 460.

Patients need not grope when buying Vitamin products!

Abbott's **HALIVER OIL**

**WITH
VIOSTEROL**

Nobody need be in the dark if Abbott's Haliver Oil with Viosterol is prescribed. For it can be depended upon to provide Vitamins A and D in the amounts claimed on the label. Methods and assays used throughout the manufacture of this Abbott specialty are your assurance.

Rigid bio-assays conducted by a staff having long and distinguished experience in the vitamin field establish the potency of each lot of Abbott's Haliver Oil. Then from released lots samples are kept and assayed at intervals to verify the stability of the Abbott product awaiting your prescriptions on the druggists' shelf.

Moreover, Abbott maintains beginning-to-end control of production. Also of much importance to you and your patients is the fact that Abbott's Haliver Oil with Viosterol is an original research product, and so has behind it many years of research and manufacturing experience of uncommon extent and character.

Prescribe Abbott's Haliver Oil with Viosterol for growing children, pregnant and lactating mothers, and all other patients who for any reason require additional amounts of Vitamins A and D. Available at prescription pharmacies everywhere in soft, tasteless, 3-minim capsules in boxes of 25, 100 and 250; and in 5-cc. and 50-cc. vials with special droppers.

Subscription prices, \$5 (\$6 for foreign countries); single copies, 50 cents.

Volumes begin with the first of January and the first of July. Subscriptions may commence at any time.

Change of Address.—Request for change of address should give both the old and the new address. No change in any address on the mailing list will be made until such change is requested by county secretaries or by the member concerned.

Responsibility for Statements and Conclusions in Original Articles.—Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. It is aimed to permit authors to have as wide latitude as the general policy of the Journal and the demands on its space may permit. The right to reduce or reject any article is always reserved.

Contributions—Exclusive Publication.—Articles are accepted for publication on condition that they are contributed solely to this Journal. New copy must be sent to the editorial office not later than the fifteenth day of the month preceding the date of publication.

Contributions—Length of Articles; Extra Costs.—Original articles should not exceed three and one-half pages in length. Authors who wish articles of greater length printed must pay extra costs involved. Illustrations in excess of amount allowed by the Council are also extra.

Leaflet Regarding Rules of Publication.—CALIFORNIA AND WESTERN MEDICINE has prepared a leaflet explaining its rules regarding publication. This leaflet gives suggestions on the preparation of manuscripts and of illustrations. It is suggested that contributors to this Journal write to its office requesting a copy of this leaflet.

EDITORIALS†

THE 1937 LEGISLATURE IS IN SESSION

The Legislative Calendar.—The biennial session of the California Legislature, which began on Monday, January 4, will hold daily meetings up to February 1 to permit submittal of proposed laws; after which it will adjourn for thirty days to allow the assemblymen and senators to return to their homes for study and discussion of legislative matters, when both houses will reconvene on March 2, to continue the session until final adjournment, probably in May or June.

* * *

The Onerous Task of the Committee on Public Policy and Legislation.—What kind of contemplated statutes affecting public health interests will be thrown into the legislative hopper during the January meetings no one can foretell with accuracy; but there need be little doubt, in days of such social unrest as these, that new and even startling types of laws will be suggested.

In past legislative sessions, proposed measures having to do with public health matters usually were numbered, not by ones or tens, but by hundreds. The task of the Association's Committee on Public Policy and Legislation, therefore, is made doubly onerous because almost every bill introduced, no matter how innocent its title or seeming purport, must be carefully read—both at its introduction and later in course through committees—to make certain that no provisions inimical to the public health interests of the State are included. What such responsibility means to those upon whose shoulders this heavy duty has been thrust, is well understood by members of the Council; but as to members of the California Medical Association, in general (more than five thousand in number), it is a question whether many are likewise alert to the great labor involved.

* * *

How Component County Societies Can Aid. It is hoped, then, that the officers of the component county societies and the delegated local committees on legislation will maintain an active interest throughout the entire legislative session, respond-

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

ing promptly when called upon for definite tasks; and that they will be especially active during the February intermission, in reestablishing cordial relationships with both senators and assemblymen representing their localities. To this end, the Association will aim, through bulletins, to keep component county societies informed concerning each important matter.

* * *

Some Probable Proposed Laws.—"Old and new friends" which, in all probability, will thus be dropped into the legislative basket, in more or less revised form, include measures such as

- Compulsory Health Insurance;
- Voluntary Health Insurance;
- Opening County Hospitals to Pay Patients;
- Opening County Hospitals to Non-Indigent Patients (without pay);
- Compulsory Hospitalization;
- Voluntary Hospitalization;
- Antivivisection bills;
- New Cultist Healing Art Board or Boards;
- Amendments to Medical Practice Act;
- New Nurses' Examining Board; and
- Amendments to Numerous State Public Health Laws.

The above brief list of law proposals quite possible should indicate why every physician who desires to see the standards of scientific medicine maintained and promoted should attend the meetings of his county society during the next several months, to hear reports as to progress on legislation, and also to enable him to aid his officers and colleagues in the work ahead.

In next month's issue a digest of some of the more important bills will be presented. In the meantime, alertness and cooperation on all sides should be in evidence.

INDIGENT CAMPS IN CALIFORNIA: A NEW AND PRESSING PROBLEM

California's Lure to Indigents and Near-Indigents.—The varied climatic attractions and agricultural and other interests of California for years have brought within its borders an unusually large number of individuals, from many states, belonging to the indigents or near-like aggregations; who, on account of the conditions under which they join with one another in groups, and their manner of living, have come to present rather a serious social and sanitary problem. During travel of any extent, by train or auto, for example, one is almost certain to see by the wayside such migratory bands; so that to members of the medical profession, accustomed to sober thought, serious misgivings must arise concerning the extent to which such nomadic persons endeavor to observe laws having to do with the protection of water supplies, and other important sanitary matters.

In agricultural districts, where ripened crops demand manual attention, many of these itinerant near-indigents find temporary abiding places, some

indeed making regular tours from one district to another, as different crops reach maturity. This mode of living is more or less haphazard; yet to a large number of persons of such roving disposition this life in the open evidently has a strong appeal. At times, these hither-and-thither men organize among themselves, subletting their group to individuals who, in turn, make it a business to supply agricultural districts with man-power (occasionally women and children as well as men) to harvest the crops of fruit, cotton, beans or other products of the soil.

* * *

Conditions Which Exist in Some Camps.—Housing arrangements for such transient laborers rarely measure up to proper sanitary standards; and, as a matter of fact, regarding the preparation of food, protection of drinking water and utensils, provision of cots or beds that are free from vermin, sanitary toilet facilities, and an inspection or examination of the persons themselves, to facilitate segregation of those who have communicable diseases, recent investigations indicate that conditions are often little short of deplorable.

* * *

Problem Has Been Presented to California Medical Association Council.—This increasing menace from camps of persons so grouped together, and perhaps doing little or no labor has led the California State Board of Health to institute measures for better supervision of such unofficial camps, to the end that the campers, and also the public in near-by communities, may be better protected. To inaugurate proper sanitation necessitates a certain amount of paternalistic medicine, not only of a preventive but a curative type; and because of that fact, the State Health Board's plans of procedure were some time ago outlined to the Council by its president, Dr. Howard Morrow.* Since the public county hospitals are open only to persons who have been residents in California for one or more years, these indigents are not eligible to admission there, and the question therefore immediately and naturally arises, "Who, then, shall care for these roving strangers?"

* * *

Component County Societies Invited to Aid. The Federal government is cooperating with the State in trying to work out a solution of the problem, and it is hoped that the component county societies in the districts involved will likewise see their way clear to work hand in hand with the representatives of the State Board of Health, for protection of local health interests, and to make unnecessary the inauguration of measures partaking of the nature of state medicine. County societies and members who are interested are invited to communicate with the State Director of Public Health,[†] regarding a betterment of the

* See CALIFORNIA AND WESTERN MEDICINE, December, 1936: Council minutes, item 6, page 503.

† The address of the State Director in the San Francisco office of the Board is printed under "Miscellaneous California Medical Organizations," on advertising page 6.

local conditions discussed, in so far, at least, as they may have come under their observation, and any practical suggestions will be welcome.

* * *

A Case in Point: Proposed State Law.—The extent to which this problem has already been called to the attention of lay organizations may be appreciated by mention of a communication which came to us from an attaché of the Los Angeles City Health Department only two days previous to this writing. This physician, a woman, telephoned for information on the subject, being desirous of knowing more particularly whether the supervision of these camps should be under the California Department of Public Welfare or the California State Board of Health, and stating that, at a club meeting which she attended, a resolution was presented to have this sanitary problem placed under the Department of Public Welfare through statutes to be submitted to the legislature, which is now in session. On her motion, action on the resolution was postponed until the next meeting, to permit her to secure more information.

We have here an example of how bodies of laymen become intimately identified with work in preventive and curative medicine, when physicians fail to be alert in the solution of public health problems. Each such foothold by nonmedical interests, in matters medical, makes a firmer foundation for propaganda efforts in behalf of state medicine. The duty of the organized profession in these premises would therefore seem to be quite plain, and it is hoped that each component county society, through a proper committee, will actively participate in all reasonable measures to advance a solution of the problems involved.

THE FIGHT AGAINST SYPHILIS: LONG-DELAYED, BUT OFF ON A GOOD START

The Incidence of Syphilis.—Syphilis, a disease afflicting about 5 per cent of American citizens (about one adult in ten being infected during his or her lifetime), and estimated by the United States Public Health Service to have 683,000 victims in the Union who are under constant medical care, bids fair at last to lose part of its prestige as one of the "captains of the men of death," represented by the five dread horsemen—heart disease, cancer, pneumonia, tuberculosis, and syphilis.

* * *

Surgeon-General Parran's Campaign Against Syphilis.—Substantiation for this statement rests largely upon the assumption that the efforts of Surgeon-General Thomas Parran of the Federal Health Service—to educate the American people and the American press to speak openly of syphilis as a public health menace that should and must be overcome—will be successful.

If Doctor Parran's campaign against syphilis were limited to his own writings in lay publications or official bulletins, we would not be optimistic enough to make the above statement. The

two new factors that give hope of a happy outcome are, first, that the time is ripe for a well-organized campaign against the disease; and, second, the federal Social Security Act will make available for the promotion of state and local health service for the next twelve-month period the sum of eight million dollars, a goodly portion of which can be allocated to the work in which Surgeon-General Parran, who for ten years was chief of the Division of Venereal Diseases of the United States Public Health Service, is so greatly interested.

* * *

The Strong Support in the Fight.—An educational campaign, sponsored by the national government, acting through the state boards of health, and ramifying down through local health agencies as represented in county and city health departments, and with ample financial means to inaugurate and demonstrate the value of scientific clinical procedures, is a something quite different from that of previous random onslaughts against lues.

* * *

Fracastoro's Contribution.*—The introduction of the word, "syphilis," brought into being by Fracastoro, the astronomer-medical scientist-humanitarian (1478-1553*), is not without romance. In the year 1530 he printed the medical poem, entitled *Syphilidis sive de Morbo Gallico*, so calling a mythical sheep herder who supposedly became the first victim of the dread disease, because he had defied Apollo during a long drought; and now the name of the fictitious shepherd is that of the dread scourge, although it must be assumed that the exact origin of the malady is still unknown.

* * *

Other Theories of the Origin of Syphilis.—The soldiers of King Charles VIII of France defeated themselves in their Italian Campaign (1493) by becoming victims of the disease, wherefore the Italians call it the French disease, and the French, in retaliation, referred to it as the Neapolitan disease; while others, because of the return of Columbus from America at that time, attributed the scourge to "Lo, the poor Indian." All of which supposed origins, however, are probably in error. But whatever may have been the beginning, there can be little doubt that among the white race, during the last four centuries, the family tree of practically every human being has been more or less tainted by syphilis (explaining, perhaps, why the lesions of the present day are less destructive and horrible than those depicted several centuries ago).

* * *

Pioneer Work of the American Social Hygiene Association: Director William F. Snow, Formerly of California.—One of the agencies to which much credit must be given for consistent and effective pioneer work against syphilis is the

* See articles on Fracastoro in *CALIFORNIA AND WESTERN MEDICINE*: October, 1930, page 739, and November, 1931, page 467.

American Social Hygiene Association, of which a former and beloved director of the California State Board of Health, Dr. William F. Snow, has long been general director. It was Doctor Snow, also, who gave earnest support to the legislative appropriation for a survey of tuberculosis in California, the State Commission's report resulting in the establishment of the Bureau of Tuberculosis of the California State Board of Health, providing as well for state subsidies to counties, out of which have come county sanatoria nowhere surpassed in the United States.

* * *

The Lesson to Be Learned from the Fight Against Tuberculosis.—There may be those who are pessimistic concerning the outcome of the fight against syphilis. For such, reference need only be made to the federal death rate reductions for that other dread malady, tuberculosis, from 201 per 100,000 population in 1900 to 71 per 100,000 population in 1935. In California, a considerable number of physicians who were key-men in the struggle against that disease are still in practice. As late as almost up to the year 1910, one of the large daily newspapers of Los Angeles refused to print articles with the word "tuberculosis," sent in by the Southern California Association for the Study and Prevention of Tuberculosis (the eighth antituberculosis society to be organized in the United States); so that, pitiable though it is to have to admit, such euphemisms and elegant refinements as the "great white plague" were necessary to secure space in its columns.

This experience, when coupled with the lowered death rate and other phenomenal progress made against tuberculosis the last twenty-five years, should be reassuring to those who now take up the gage of battle to carry on a similar propaganda against an equally malignant disease—syphilis. If well-considered action and plans are joined with diplomatic firmness, it will not be long before the national and local broadcasting stations (guilty of so much atrocious and dangerous misinformation sent out over the air by clients promoting medical frauds at the expense of an unsuspecting public) will modify their rules that the "offensive word" syphilis, shall not pass on their sound waves. So, also, will one newspaper after the other, in good and not far-distant time, also revoke the rule not to print the word syphilis or accept news items on the subject.

* * *

A Very Recent Experience.—In this connection it may be of interest to state that at Los Angeles on December 19, 1936, was formed the Southern California Association for the Study and Prevention of Syphilis and Gonorrhea. It was a tribute to the intelligence and earnestness of the large lay group of clubwomen who were present to take part in the organization of the society, that they urged an abatement of the hush-hush policy about the diseases, and that, after much discussion, the names, syphilis and gonorrhea, were included in the title of the Association; and this, in spite of the fact that press representatives

who were present stated their publications could give no publicity with those words attached! Which again leads us to think that we are on the eve of a long-desired, successful battle against a disease which the Scandinavian countries, for instance, have been able to subjugate, and which should, therefore, be the more possible for us to vanquish, at least in good part.

* * *

California Medical Association Department of Public Relations Sponsors the California Fight Against Syphilis.—In the Association news columns of this issue,[†] this subject is also discussed. The Department of Public Relations of the California Medical Association is giving active support in the educational work, as evidenced in Chairman Charles A. Dukes' letter printed in this issue.[†] In this fight, the members of the medical profession have very definite obligations; and it should never be said, when the story is told, that physicians in California were found wanting!

VALUE OF BASIC SCIENCE (QUALIFYING CERTIFICATE) LAWS: AS PROVED BY EXPERIENCE

An Important Contribution in Factual Information Concerning Basic Science Laws.—At the 1936 conference of state medical association secretaries and editors, recently held under the auspices of the American Medical Association at its Chicago headquarters, an illuminating address on "Qualification in the Basic Sciences" was given by J. William Holloway, an attorney and member of the American Medical Association Bureau of Legal Medicine and Legislation. Part of its value lay in the fact that the actual experience of the ten states which have enacted basic science laws (Connecticut in 1925; Wisconsin in 1925; Washington in 1927; Nebraska in 1927; Minnesota in 1928; District of Columbia in 1928; Arkansas in 1929; Oregon in 1933; Iowa in 1935; and Arizona in 1933, this law invalid, and 1936), without exception emphasizes not only the value of basic science (qualifying certificate) laws for states having multiple healing-art examining boards, but gives indication that in the not far distant future, in self-protection, all commonwealths with multiple boards will be obliged, in all probability, to enact just such legislation, to prevent the influx of cultist practitioners unable to secure licenses from their respective boards in states having basic science laws.

* * *

The First Basic Science Laws: Studies in California.—Connecticut was the first, and Wisconsin the second state to secure such legislation, to be followed by Washington and Minnesota; and on page 525, in the October, 1927 issue of CALIFORNIA AND WESTERN MEDICINE, comment was made editorially on the new types of statutes which those commonwealths had brought into being in an effort to protect lay citizens from

[†] See page 47, and also Letters, page 61.

healing-art practitioners deficient in that fundamental education so necessary for the proper understanding and interpretation of physiologic and abnormal bodily function. In Los Angeles, a local committee, after study of a possible basic science law, drafted such an act, and, for purposes of education and determination as to legislators' reactions, submitted it to the California Legislature on January 17, 1929, as Assembly Bill 666. At the meeting of the California Medical Association Council held on January 18, 1930, we made a motion for the appointment of a special basic science act committee,* and during the years that have since elapsed this special committee† has made one or more reports annually; both the time and conditions, however, proving unfavorable to the enactment of such legislation.

Two years ago, again, to test out public and other opinion, another draft of a qualifying certificate act, having the number A. B. 1552, was introduced as a legislative measure. In its consideration in the California Assembly, many amendments were attached to it by various interested parties, and no effort was made to bring it out of the assembly committee's hands.

* * *

In California, a Basic Science Act Must Be an Initiative Law.—Renewed study of the problem has brought the conviction that in California a qualifying certificate (basic science) law, that would include osteopathic and chiropractic practitioners as well as physicians and surgeons, must of necessity be an initiative law, because the existing osteopathic and chiropractic acts were enacted through initiative vote of the electorate, and only an initiative law can amend them. If, therefore, the State of California desires a qualifying certificate (basic science) law that will apply alike to each of the existing three California healing art laws, such enactment can be made only by an initiative vote of the citizenry of the State.

* * *

The California Medical Association Referendum in 1935.—The Council in 1935 asked the members of the California Medical Association, in a referendum vote, to express their opinion on the need of a basic science law, the final vote being 2,049 for and only 263 against the proposal to expend the necessary monies to place such an initiative on the 1935 state election ballots. At that time, a total of 186,378 valid signatures was necessary for such placement; but, because of the larger number of citizens who voted in the November, 1936, state and presidential election, a larger number of valid signatures will be required if a qualifying certificate law is to be placed on the state election ballots of the current year.

* See Minutes, item 30, CALIFORNIA AND WESTERN MEDICINE, April, 1930, page 288.

† The Special Committee's officers are listed on advertising page 6 of the current issue.

A list of references to reports and comments on qualifying certificate laws was given in the November, 1935, issue, page 383, and is here noted for the convenience of readers who wish to acquaint themselves with the subject.

Subject Worthy of Earnest Consideration by County Societies and Members.—The attention of component county societies and of their members is again called to this proposed legislation, because no State in the Union is in greater danger from new groups of cultists than California.

It is reassuring to know that the tentative draft of the California qualifying certificate (basic science) act fulfills, in large measure, the requirements which are emphasized by Mr. Holloway in his American Medical Association address.

* * *

Some Excerpts from Mr. Holloway's Address.—Because of Attorney Holloway's intimate knowledge of the various laws, we close these comments with some quotations from his paper, and suggest their perusal by all readers:

The legislatures in the several states had, in the exercise of their police power, enacted laws which are known as medical practice acts, prescribing certain qualifications to be possessed by persons who desired to treat the sick. As medical schools in this country developed to a higher degree of efficiency, and as the need for a greater protection of the public health became more evident, the requirements exacted of would-be practitioners of the healing art became higher and higher. But as the conditions precedent to medical licensure became, in the interest of public protection, more exacting, there arose demands on the part of certain groups of would-be healers for special recognition. These demands were predicated on theories of healing that, it was argued, did not necessitate the same degree of proficiency in medicine as was prescribed by the various medical practice acts. The truth of the matter is, of course, that these groups were incompetent to meet existing requirements, and in order lawfully to practice, it was necessary that they either seek to lower the requirements contained in the medical practice acts so that they could qualify thereunder, or obtain special practice acts for themselves. . . .

‘ ‘ ‘

To examine applicants for certificates of proficiency in the basic sciences, an impartial, nonsectarian board of examiners is created, composed of teachers in the subjects on which applicants are to be examined. . . .

‘ ‘ ‘

The basic science requirement does not apply to practitioners who are legally practicing the healing art in the State at the time of the passage of the act. It applies only to those persons who, subsequent to the passage of the act, seek licenses so to practice. The practice of the healing art is defined in a basic science act in broad, general language. The definition that is advocated is broad enough to include within its scope all modes of practice, by whatever name known. It is necessary, therefore, that those groups not desired to be included in the act be specifically exempted from its requirements, such as dentists, chiropractors, optometrists, etc. . . .

‘ ‘ ‘

Basic science laws, when nondiscriminatory in their provisions and when impartially administered, have met with the approval of the courts on the same ground as have medical practice acts; that is, they constitute a proper exercise by the State of its police power. . . .

‘ ‘ ‘

One yardstick by which the worth of legislation may be measured is the opinions, in retrospect, of its sponsors. . . .

And there is reason enough why basic science laws are regarded so highly in those states that have enacted them. The results of the basic science examinations indicate clearly indeed that poorly equipped persons are experiencing great difficulty in obtaining licenses in such states. A group of better practitioners follows as an inevitable sequence to the enforcement of a basic science requirement. . . .

~ ~ ~

The enactment of a basic science law not only will reduce materially the number of incompetents who annually receive licenses to practice the healing art, but will discourage attempts by other groups to gain a foothold in the State—groups not recognized by law at the time of the enactment of the basic science act. . . .

~ ~ ~

Some of the states have found that convictions are easier to obtain under the basic science Act than under the provisions of the medical practice act. . . .

~ ~ ~

To establish the most effective barrier against incompetent healers, let me repeat, the basic science act should be nondiscriminatory and nonsectarian. It should not be loaded with provisions that will tend unnecessarily to intensify the opposition to enactment and to invite future difficulties without producing any material present benefits. . . .

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 47.

EDITORIAL COMMENT†

TESTS TO DETERMINE THE CURABILITY OF GONORRHEAL URETHRITIS

In this day and age it is astounding to know that many physicians still think the urethra is lined with asbestos, and not with a delicate mucous membrane which is wilfully subjected to more trauma than any other accessible mucous membrane of the body.

It has been a custom for many decades, and still is today, that, to discharge a patient as cured of his gonococcal infection, the urethra should be subjected to the most gruesome tests. As a result of these tests, which will be enumerated, a cured case of gonorrhea is not only prolonged, but subject to complications, namely: stricture, chemical and instrumental urethritis, vesiculitis, prostatitis, epididymitis and cystitis.

We spend two to three months building up a tissue resistance against the invading gonococcus, only to find that one or two injections of silver nitrate, a vigorous massage, or a forced introduction of a sound has prevented us from obtaining

a cure. The injection of a strong silver nitrate solution as a test to determine the permanency of a gonorrheal cure should be condemned. The suffering and torture produced by this chemical is well known to the patient, and the possible complications enumerated above should be borne in mind by the physician. Silver nitrate solution should be used only in the treatment of gonorrhea, and not as a test to determine a gonorrheal cure.

If one wishes to use a sound in the terminal stage of gonorrhea, he should choose the correct caliber and be gentle in its passage. The sound should be guided and not forced into the urethra. Suffice it to say that Keyes' warning, "Oh, so gentle!" in passing a sound, is of paramount importance.

Vigorous massage of the prostate may not only make the patient "jump like a frog" or "see black before his eyes," but may result in an acute prostatitis, vesiculitis, and epididymitis. By applying firm, gentle pressure on the prostate, the secretion obtained can be examined for gonococci.

Since repeal of the Prohibition Act, the beer test is again coming into vogue. The patient may detest beer, but nevertheless he is told by the physician to "guzzle" down several glasses upon retiring and to repeat it for three days. He is then asked to report in the morning for any possible discharge. He may not only become a confirmed beer drinker, but his entire genito-urinary tract and gastro-intestinal tract is subjected to unnecessary abuse. In reality, barring complications, the urethra is the site to be tested for the infection.

In conjunction with the above tests, one may resort to the complement fixation test, and to the examination of a centrifuged specimen of urine, which the patient has voided in the morning.

If we could only realize the number of patients who come to our offices with unnecessary urethral discharges and complications, as a result of these local abusive methods of determining the curability of gonorrhea, the economic, social, and domestic aspects of the situation would be materially benefited.

RELATIONSHIP OF TURBINAL ENLARGEMENT TO SEPTAL IRREGULARITIES

During the past ten years it has been the occasional experience of the writer to have patients return after septum resections had been performed, either by him or by others, with the apparently illogical complaint of impaired breathing on the hitherto good side of the nose. To illustrate: If the septum operation had been done to correct a nasal obstruction on the patient's left, after a certain lapse of time, the patient would return stating that although his left side was perfectly clear, his right side, which prior to the operation had been open, was now impaired.

Analysis of the factors involved would seem to indicate these symptoms not to be so unreason-

able. Attention has long been directed to the association of enlarged turbinates with the concavity of deviated septums, but sufficient emphasis has not been made upon the correction of this enlargement at the time the resection is done.

With a septum deviated to the left, the breathing space is narrowed on the left and, conversely, is widened on the right. The right inferior turbinate will therefore enlarge, since it seems to be a corollary for the turbinate to enlarge in a compensatory manner and thus narrow down an excessively wide space within the nasal chamber in order to contact a maximum of air that may pass through it.

If the condition has been of short duration, this turbinal enlargement can be classified as an engorgement and, after the septum resection has been performed, will eventually spontaneously shrink down more or less to somewhere within its former size. However, if the enlargement has been long standing, there evolves a tendency toward chronicity and this condition can be classified as hypertrophy or hyperplasia.

Recapitulating the points brought out so far: If the septum is deviated to the left, causing an unusually large breathing space on the right, the right inferior turbinate will enlarge in a compensatory manner to fill the concavity on its side caused by the deviation. However, after the operation this concavity is destroyed, since the septal mucosa now hangs down as a straight partition. Inasmuch as the turbinate is hypertrophied, there is no spontaneous return to former size, and the hitherto good side of the nose is now the one of which the patient complains.

It would appear that differentiation between engorgement and hyperplasia, prior to the septum operation, would clarify the situation and point toward the proper method of procedure. The standard technique is well known—that of applying a weak solution of cocaine to the turbinate under consideration. Shrinkage of the tissue within five minutes would designate the enlargement as a temporary engorgement. However, if the turbinate shows no, or only only a small, change in size within that period of time, we know we are dealing with a true hyperplasia, and attention toward this condition is indicated before the patient is discharged.

HISTAMIN AND EPINEPHRIN TESTS

EPINEPHRIN:

The minute vessels which color the skin contract in the presence of adrenalin, producing an area of pallor. If the venous return from a limb be obstructed by a sphygmomanometer cuff, the pressure in the veins and, therefore, in the venous end of the vessels which color the skin, will build up to the pressure in the cuff. In this way it is possible to measure the contractile power of the minute vessels. In general, this is of the same order as the resting-blood pressure, but is found

to be lower in areas that have recently been exposed to injury, irritants, or burning by heat or light and in those areas such as the face which habitually suffer the minor insults consequent upon the exposure.

HISTAMIN:

Eppinger, and later Lewis, described the triple response of the skin vessels to the intradermal exhibition of histamin. The full development of this response takes from three to eight minutes.

1. *Local Reddening*.—The whole area with which the histamin comes in contact by diffusion presents a reddening due to a relaxation of the minute vessels of the skin. This reaction is commonly masked by 3.

2. *Red Flare*.—This is a widespread (1 to 2 centimeters) area of bright reddening produced by arterial dilatation as the result of an axon reflex excited by the histamin. This flare is unaffected by nerve section until enough days have passed for nerve degeneration to take place.

3. *Wheal*.—A strictly localized wheal is present, associated with a change in the rate at which tissue fluid is exuded from the blood stream.

(4. *Itching*.—As the wheal starts to form, an itching sensation is felt.)

The same factors which lower the contractile power of the coloring vessels in the epinephrin test appear to inhibit the triple response to histamin; but whereas the adrenalin response is dependent solely upon the condition of the minute vessels, the histamin responses—at least the flare and the wheal—are dependent upon the blood supply, the integrity of the local nervous vasodilator system and the relaxing power of the local arterioles.

These reactions have been used to aid the prognosis of diabetic circulatory insufficiencies, in the selection of amputation sites (McNealy and Shapiro) and in the differentiation between occlusive and spastic types of arterial disease (Kramer).

A 3-milligram tablet of histamin is dissolved in one cubic centimeter of water. A drop of this solution is applied to the skin and a single prick is made through this drop just deep enough to avoid drawing blood. After one and one-half minutes the drop of solution is gently removed by absorbing with filter paper. If several pricks are made to insure against the chance of failure, they should be through separate drops at least 3 centimeters distant from each other, in order that variations in the size of the wheal and flare may be appreciated. Some authorities recommend the intradermal injection of histamin as being more certain, but this technique makes it very difficult to examine the wheal.

The epinephrin punctures are similarly performed with 1/1000 adrenalin solution, and the cuff pressure necessary to cause the white reaction to disappear is noted.

A DENGUE-LIKE FEVER*

CLINICAL MANIFESTATIONS RECENTLY OBSERVED
IN THE SAN FRANCISCO BAY DISTRICT

By GARNETT CHENEY, M.D.
San Francisco

DISCUSSION by Donald D. Lum, M.D., Alameda; Edward B. Shaw, M.D., San Francisco; Charles W. Lane, M.D., Coronado.

A FORM of fever has recently been observed in the San Francisco Bay district which appears to differ in certain respects from any of the well-recognized disease entities commonly encountered. The manifestations are not unlike dengue fever, and the disorder has been reproduced by the intravenous inoculation of whole blood, which is also characteristic of dengue fever.¹ As it has not been possible to identify the febrile disturbance under discussion with the dengue fever of the tropics, it has been called a dengue-like fever. As the patients suffering from this form of fever are often alarmingly ill, and as certain symptoms and signs are common and apparently characteristic, a wider knowledge of the manifestations may lead to a more exact understanding of the true nature of this condition. With this end in view, an analysis has been made of the findings in twenty cases observed by the author in the summers of 1934 and 1935.

CLINICAL MANIFESTATIONS

As the diagnosis in this group of cases cannot be substantiated as yet by any known specific test, its accuracy may of course be questioned. It has been based on the presence of certain symptoms, the absence of leukocytosis, and an inability to prove that any known disease entity was the cause of the patient's illness. Only those cases have been included which have met these requirements. It was also taken into account that all these cases

Fig. 2.—The incidence of the common clinical manifestations in twenty cases of the California dengue-like fever.

appeared in the summer months, except for a few in the late spring or early fall. This seasonal incidence is presented graphically¹ in Figure 1, and shows a peak in July and August; but the number of cases is too small to justify any detailed analysis.

The important clinical manifestations are listed¹ in Figure 2 in the order of their frequency. Nearly all of these twenty patients were young adults, but the age incidence varied between seventeen and sixty years. There were eleven males and nine females. A fever of 103 degrees or over was present in eighteen of the patients. In the other two it reached 102 degrees. At times it was well sustained, and in other cases it was very irregular. (Figures 3 and 4.) It was pronounced for six to eight days in every instance, and frequently fell to normal for a number of hours on the third or fourth day. It was occasionally higher during the second half of the illness than the first. Slight daily rises sometimes occurred for as much as a week after clinical recovery. The commonest symptom was a severe headache, which was a major complaint in 85 per cent of the sufferers. It was frequently frontal in location, but sometimes generalized or occipital. It was unusually, but not invariably, most intense early in the illness. It was so severe in four patients that lumbar puncture was performed. The spinal fluids were negative.¹ Figure 2 shows that the next most prominent symptom was severe backache, which was often most intense in the sacro-iliac regions, and seemed far worse than that commonly encountered in the other febrile disorders. It was present in all but three cases.

NATURE OF THE ONSET

One of the striking features of this dengue-like fever was the abrupt onset of the illness. Three-fourths of the patients could state almost to the hour when they became ill, and most of them had felt perfectly well previously. Another impressive characteristic was the presence of pains in the limbs which was noted in 70 per cent of the cases. These pains were so acute in some individuals that they would lie perfectly quiet, afraid to move. In some the joints were also stiff and pain-

Fig. 4

ful. Three patients were at first thought to be suffering from trichinosis. The term "break-bone" fever seemed justly applicable. An outstanding finding in this group of cases was the white blood cell count. In only one instance were there over 10,000 leukocytes present, and then there were 12,000. It should be emphasized that this absence of leukocytosis was exhibited in the presence of high fever. Even more unusual was the presence of leukopenia (white blood cell count less than 6,000) in 60 per cent of the cases. The lower white cell counts tended to occur in the latter part of the illness. The lowest count was 2,800.¹ Follow-up leukocyte counts were not carried out.

INTERESTING SYMPTOMS

Slightly over half the patients presented a definitely biphasic illness. Not only was the fever abated on the third or fourth day, but all prostration and aching would disappear and the patient would feel that he had recovered. This false sense of well-being would last but a few hours to a day, before symptoms would return which might differ in nature or be more violent than in the first episode of the disease. Such a secondary exacerbation may be considered quite characteristic. Half the patients were irrational at some time during their illness, and the mental disturbance tended to occur in those with the highest fever. In five instances the delirium, together with other symptoms, strongly suggested typhoid fever. Blood cultures and Widal's were negative in each. Forty-five per cent of the patients complained of photophobia, which usually lasted two

or three days. In the majority of these conjunctivitis, palpebral edema and soreness of the eyeballs accompanied the sensitiveness of the eyes to light.

At some time during the course of the illness, nine patients presented an enlargement of the lymph glands which was usually generalized. Cervical and postauricular adenopathy were often the first noted. The glands were not over 2 centimeters in diameter, discrete and not tender, and tended to subside during the convalescence. A major complaint in 40 per cent of the cases was a violent chill. In some this was a single occurrence at the onset of the fever or during the second effervescence. However, three patients ran what may be aptly termed a septic course of fever, with repeated chills occurring two or three times a day and followed by drenching prostrating sweats. Another characteristic and very troublesome symptom was the itching which tormented a third of those ill. It appeared late in the course of the disease and persisted into convalescence, and was unassociated with rash or jaundice. Many of these sufferers scratched themselves badly. A definite erythematous, macular or urticarial rash was present in six patients, appearing either at onset or on the fourth or fifth day of illness. In no instance were the skin lesions germane to drug therapy. The last common manifestation of this dengue-like fever listed in Figure 2 is jaundice. It appeared during the last part of the illness in one-fourth of the cases and was never intense. The icteric index ranged from fifteen units to thirty units. The icterus persisted about two

weeks. The liver was palpable and tender in two of the five jaundiced patients.

OTHER FINDINGS

Certain other findings of interest were encountered in a few patients. A loss or perversion of the sense of taste, anorexia, nausea, vomiting, constipation, and abdominal pains were relatively rare gastro-intestinal complications. The tongue often showed a thick, creamy coating. Evidence of upper respiratory-tract infection was conspicuous by its absence. Three patients developed cough, and some râles at the lung bases late in their illness; actually at a time when nearly all other symptoms had disappeared. Two of the eleven males complained of severe pains in the testicles without objective findings except moderate tenderness. Three patients had palpable spleens during the period of high fever. The pulse rate was usually increased in proportion to the temperature, but persistent bradycardia occasionally occurred. Two cases had transient albuminuria. None developed anemia. The sedimentation rates were moderately increased in the six patients upon whose blood they were performed.

DIAGNOSIS

Trying to paint a picture of a disease on paper is inadequate compared with the clinical examination and study of patients under a physician's care; however, this description strongly suggests that a disease entity new to the San Francisco Bay region has made its appearance. At present the diagnosis must be based on a fever of fairly high degree, and of about a week's duration, accompanied by prostration, severe aching and certain other symptoms as enumerated, and the white blood cell count must be normal or low. Evidence of respiratory tract infection is characteristically lacking, and the disorder typically appears in the summer months. The complete differential diagnosis has been dealt with in a previous communication,¹ but it should be stated here that the chief difficulty may arise in separating this dengue-like fever from influenza. The appearance of the infection in the middle of the summer, the lack of family incidence, as all the cases reported are isolated ones, the complete lack of upper respiratory tract symptoms, and the presence of certain findings usually foreign to influenza such as the rash, itching, glandular adenopathy and jaundice, would make the diagnosis of influenza untenable in these cases.²

ETIOLOGY

The etiology of this fever is at present unknown, but it seems likely that it belongs to the group of filterable virus infections. There is no known vector, although some of the patients had been bitten by mosquitoes, and a number by fleas within ten days of the onset of the illness. A positive identification with dengue fever would of course clear up these points. The treatment of this fever is symptomatic; and the prognosis is excellent, although some patients suffered from asthenia and pains in the limbs for as long as two weeks after the acute illness.

DISCUSSION

DONALD D. LUM, M. D. (1361 Park Avenue, Alameda). Doctor Cheney has used a great deal of acumen in segregating this group of cases.

The clinical manifestations clearly fit into the group of dengue-like fevers. There are only two missing links in the absolute proof of the diagnosis. One is the finding of the vector, and the second, the definite proof that one attack will confer an immunity. I hope that Doctor Cheney will be able to inject one of these patients with blood from a future case. This would prove the presence of an immunity to this type of fever. It would be interesting, in a recovered case of proved dengue fever, to inject the blood as well to demonstrate the immunity of dengue to this entity.

Although a definite vector has not been found, there are closely related mosquitos in this vicinity which may have some bearing on the problem.

So often these patients are placed in the general diagnostic basket of influenza. With the spontaneous recovery of the patient, they are considered as such, without further thought. Influenza can be definitely ruled out in this group by the presence or absence of the symptom-complex, as discussed by Doctor Cheney.

With our rapidly increasing migratory population, we are very apt to have an invasion of tropical and sub-tropical diseases. The itinerants may bring in not only the etiologic factor, but the vector as well. It behooves us all to consider these factors in our differential diagnosis.

✱

EDWARD B. SHAW, M. D. (384 Post Street, San Francisco).—Most of us are prone to accept undiagnosed febrile illnesses of short duration as influenza, the definition of typhoid as "intestinal influenza of three weeks' duration" is almost pathetically true. The correction of similar mistakes is illustrated in the history of medicine; measles was finally differentiated from smallpox, typhoid was gradually distinguished from typhus, and more recently relapsing fever was identified among just such a group of cases as this paper describes. There is, of course, the contrary possibility that a number of different infections may be erroneously classified into a single syndrome.

In a majority of these patients, at least, there seems to have been a fair degree of correlation of symptomatology and clinical findings, and convincing evidence of the absence of any of the commonly recognized disease entities. The disease seems not demonstrably to have spread by contact, and yet could be transferred by inoculation of blood. The possibility naturally presented that the disease is spread by an insect vector is an intriguing one, but the paucity of biting insects which frequent San Francisco fails to support this idea. We have few mosquitos and certainly do not have recognized vectors of dengue fever. Portola was probably the first to comment on the size and voracity of the San Francisco flea, but the infection just described has hardly been sufficiently widespread to suggest that the flea is the responsible vector.

Certain points of similarity exist between this disease and exanthum subitum, a common disease of infancy. I would not propose that the two diseases are identical, but both are characterized by low communicability, high fever of short duration, splenomegaly, adenopathy, and a rash. In both the etiologic agent is unknown, and the diagnosis depends entirely on clinical differentiation.

If one might paraphrase a well-known, but nonmedical, authority, there must be many things not comprehended in the philosophy of modern medicine. Progress in medicine proceeds not only from the laboratory. The frontiers of medical knowledge lie at every bedside, and accurate observation, intelligent correlation, and the insistent search for truth will inevitably lead to new clinical discoveries of no less value than those which come by way of the more exact sciences.

CHARLES W. LANE, M.D. (102 Bank of Coronado Building, Coronado).—I have been interested in Doctor Cheney's paper for two reasons: First, because he is dissatisfied with our usual method of classifying all influenza-like fevers simply as influenza without making any real effort to establish positive diagnoses and, in the second place, because the peculiarities of dengue fever and its possible occurrence in regions hitherto unaffected are points that should be given general recognition.

If the cases described by Doctor Cheney were dengue fever, I am sure there would have been a real epidemic with probably many thousands reported, as is customary when this illness attacks a non-immune area. Dengue cases appear in the same house or in near-by houses, and rapidly spread in all directions through the community. The appearance of widely isolated cases would be difficult to explain, as the carrier is a house dweller and does not usually travel great distances.

It has been shown that a temperature of 64.4 degrees Fahrenheit destroys the virus in the mosquito. The summer months in San Francisco are generally quite cool, and it is not uncommon for the temperature to remain below this point for a considerable time.

Except in rare cases, dengue is not ushered in with a real chill, but with chilly, "grippy" sensations. The leukopenia in dengue is not only relative but definite, the average patient dipping down to five thousand or less. A rash in dengue is found in a larger percentage of cases, and it might be of interest to note that frequently cases of dengue are said to have no rash when a careful examination will reveal one along the extensor surface of the great toe. Itching is infrequent, and jaundice occurs in a very small percentage of cases.

The sudden onset, violent aching, short duration of fever and the tendency to a temperature curve of the camel-back type, together with a rash, would naturally cause Doctor Cheney to think of dengue, but it seems obvious to me that he was dealing with some other disease.

One interesting fact that I have never seen mentioned in any article on dengue fever is that so many who have had it will notice for a year or more following, that at intervals of from four to six weeks there is an afternoon and evening recurrence of general aching. It would be interesting to know for how long a period the blood remains infective.

It is, of course, possible that the airplane will introduce dengue to any community harboring the proper mosquito at a time of year when the temperature is above 64.4 degrees Fahrenheit.

BASAL METABOLISM*

DETERMINATION OF THE ZERO POINT IN A NORMAL GROUP IN SOUTHERN CALIFORNIA

By JOHN MARTIN ASKEY, M.D.
Los Angeles

DISCUSSION by Clarence G. Toland, M.D., Los Angeles; H. Clare Shephardson, M.D., San Francisco.

THE value of the basal metabolism test depends upon the degree of variation from the normal and upon the proper clinical interpretation of this variation.

In Southern California we are concerned with the variation of the determined basal metabolism from that of normal persons in Southern California.

Up to the present the basal metabolic rate has been compared with the standards for normal as determined in Washington, New York, and Boston.

We wish to give the results of a study of 108 normal persons in Southern California to ascer-

tain the range of the basal metabolic rates in a normal group in this climate and in this particular population.

CHOICE OF A STANDARD

What standard shall be used in computing whether or not a certain oxygen consumption is above or below the normal consumption? The choice of an improper standard can make a marked difference in the basal metabolic figure. If a normal person has a basal metabolism of zero according to the Mayo standards, it would be plus nine according to the Krogh standards. A basal metabolic rate of zero by the Harris-Benedict formula is minus 6 when calculated by the Aub-Du Bois standard. It is surprising that figures are reported in the literature almost invariably with no statement as to the standard used. A correction factor is always necessary in order to compare figures obtained by different standards. Tables 1 and 2 show the correction factors as determined by Jenkins.

These differences exist not only because some are based on surface area figures and others on weight, but also because there are actual differences in the levels of normal groups in different localities. Even if a single standard is employed, normal groups in different sections of the country will show varying levels.

Before any figures for oxygen consumption can be compared with any standard without the likelihood that there will be an error of from 1 to 9 per cent, it must be determined which of the various standards is the best when applied to normal persons.

A determination of the mean metabolism, or the zero point of a normal group, would tell whether it corresponded to the higher normal prediction values as represented by the Aub-Du Bois tables or the lower values as represented by the Dreyer standard. Use of the corrected standard would result in the elimination of several points of error.

Any conclusion drawn as to the degree of variation from normal of a basal metabolism is not correct unless the zero point from which the variation is measured is known to be correct.

NORMAL RANGE OF BASAL METABOLISM

The mean metabolism of the 108 normal persons was determined according to the standards of both Aub-Du Bois and Dreyer. These were chosen for several reasons. The standards of Aub-Du Bois are in more general use than any other, and are based on the surface-area theory. The Dreyer standards have been shown to be very accurate, and represent the standards calculating normal metabolism in proportion to the weight rather than surface area.

The dispersion of the basal metabolisms around the two zero points, as determined for the two standards, gives the normal range according to the two standards.

TYPE OF NORMALS

There were sixty-four women and forty-four men, ranging in age from sixteen to sixty. Most

of the men were business and professional men; the women were housewives, business women, and students. They represented an average cross section of the type seen in private practice. A portable Benedict apparatus, modified by the Sanborn motor blower, was used. The tests were done in Dr. C. G. Toland's office by two technicians who have been doing this work for over ten years. The average of two tests was taken, rather than the lower.

The basal metabolism of the normals must be studied under the same conditions used for clinical determinations. If one-day tests are to be compared with a standard, it necessarily should be a standard derived from one-day tests. Inasmuch as most clinical basal metabolism determinations are not done several days in succession, they must be considered as one-day tests and compared with a standard based on such tests. The Aub-Du Bois and Mayo standards are based on a high proportion of first-day tests.

ERRORS IN BASAL METABOLISM DETERMINATION

The errors that arise in basal metabolism determinations, in addition to those due to a faulty standard, are chiefly those of faulty technique and a varying basal emotional state of the patients. Technical errors account for 2 to 3 per cent error even in the best hands. Due to the long experience of our technicians, we feel that technical error was minimal. The varying basal state of even normal individuals is at times marked, and this usually accounts for the wide degree of normal dispersion.

The majority of our normals were adults who cooperated well when the test was explained.

We present this group as a representative normal group of the type seen in private practice, but not a cross section of the whole population.

THE ZERO POINT

In the group of 108 normal persons, the zero point according to the Aub-Du Bois standard was at minus 6.8. According to the Dreyer formula (Stoner's tables) the level was minus 3.4.

By the Aub-Du Boise standards, the great bulk of the normals was on the minus side of the un-

TABLE 3.—*Comparison of Aub-Du Bois (Sage) and Dreyer Standards in Predicting Basal Metabolism of 108 Normal Persons in Southern California*

	Per Cent in ±10 Range	Per Cent in ±15 Range
Sage Standards:		
(With uncorrected zero point)	60.3	84.2
(With corrected zero point) (-6.8)	74	90.8
Dreyer Standards:		
(With uncorrected zero point)	84.2	87.9
(With corrected zero point) (-3.4)	86.2	94.4

corrected zero point. Of the 108 normal persons, eighty-eight had figures below the calculated calories for normal.

The Dreyer standards gave results closer to the zero point, but even so, seventy-six of the one hundred and eight had subnormal figures.

The mean metabolism of the Aub-Du Bois standards was, consequently, lower, minus 6.8 as compared with minus 3.4, according to the Dreyer

TABLE 2.—*Correction Factors for Comparison of Standards for Women (Jenkins)*

Rate Compared	Rate Compared With					
	Krogh Per Cent	Dreyer (Observed) Weight Per Cent	Harris- Benedict Per Cent	Mayo Per Cent	Aub- Du Bois Per Cent	Bailey Per Cent

Bailey	+6	+5	+4	+1	0	0

Chart 1.—Dispersion of basal metabolism of 108 normal persons in Southern California (Aub-Du Bois standards).
●—Male
○—Female

standards. These figures are then the true zero points of these standards when applied to our normals.

A basal metabolic rate of plus 10, calculated according to the Aub-Du Bois standards, is actually 16.8 points above the corrected zero point. A figure of minus 16.8 is only ten points below the correct zero point.

DISPERSION OF THE RATES

Only 60 per cent of the normals fell within a plus 10 minus 10 range of the zero point, according to the uncorrected Aub-Du Bois standard. When the dispersion was determined with minus 6.8 as the zero point, 74 per cent fell within the plus 10 minus 10 range.

The Dreyer standards were found to be more accurate than the Aub-Du Bois standards in several ways. Not only did the zero point of our normals agree more closely with that of the Dreyer standard, but there was a more compact grouping of the normals.

Even according to the corrected Aub-Du Bois zero point, 26 per cent were outside a plus 10 minus 10 range. Only 13.8 per cent were outside this latitude, according to the Dreyer standard.

There was much more chance of the basal metabolism of our normal group falling in a plus 10 minus 10 range if calculated by the Dreyer standards than if calculated by the Aub-Du Bois standards. Similarly, more were within the plus 15 minus 15 range when calculated by the Dreyer formula.

Apparently the weight formula was much more accurate in predicting the normal metabolism in our group than the surface area formula.

Using the corrected Dreyer standards, one is reasonably sure that 95 per cent will be within fifteen points of the zero point.

Chart 2.—Distribution of basal metabolism of 108 normal persons in Southern California. Calculations made according to Aub-Du Bois and Dreyer standards.

Jenkins has shown that the relative prediction accuracy of the Harris-Benedict and the Dreyer standards are similar, so they may be considered of equal value here. The Dreyer standard has the added advantage of greater simplicity of application. A single table, as devised by Stoner, can be used instead of different tables for adults and children as needed for the Harris-Benedict tables.

We are using this standard now, and with the corrected zero point feel that we have limited materially the error due to a faulty standard and have avoided resultant clinical misinterpretation.

Regardless of the basal metabolism reading obtained, we must accept it only as a laboratory aid and always of secondary value to the clinical diagnosis. If we are to use it, it should be sharpened in every possible way as a diagnostic instrument. Even then, because of the normal dispersion, it is advisable to allow 15 points variation from the zero, instead of delimiting the normal range to 10 points. Diagnosis made because of slight variations from normal should always be regarded as questionable, but especially so unless the basal metabolism is compared with a standard, the zero point of which has been established by testing normals in that particular region.

SUMMARY AND CONCLUSIONS*

1. Every laboratory should individually determine its zero point according to the standard it uses.
2. In a group of normal persons in Southern California the zero point, based on one-day tests, was minus 6.8 according to the Sage standards of Aub-Du Bois, minus 3.4 according to the Dreyer formula.
3. The Dreyer standards apply more accurately to the normal group studied than the Aub-Du Bois standards.
4. Basal metabolism figures should always specify the standards used.
5. Deviation of 15 points on either side of the established zero point should be considered within normal range.

DISCUSSION

CLARENCE G. TOLAND, M.D. (1930 Wilshire Boulevard, Los Angeles).—For a number of years we have been interested in Doctor Askey's work.

We used to be puzzled by a lack of agreement between basal metabolic rates and clinical impressions, and some of the error in interpreting the basal metabolism was due to use of a standard established in a colder climate.

In a subtropical climate, as in Southern California, the basal metabolism is reduced normally; and unless this is recognized, faulty conclusions will be drawn. The discovery that the Aub-Dubois standard for normals predicted values nearly seven points off, when applied to normals here, led us to discard it. We have found the Dreyer standard is much better in predicting basal metabolism in Southern California, and we feel that others checking normal metabolisms here will also find it so. Standards must be chosen according to geographical location, and the only way to know is to find out by determination on normals.

Doctor Askey has done this in Southern California, and I think we can all profit from it. I want to emphasize, too, the need for always stating the standard used when reporting a basal metabolism. Only in this way can we compare rates which have been calculated by different standards.

✽

H. CLARE SHEPARDSON, M.D. (384 Post Street, San Francisco).—The importance of the data concerning determination of the so-called "zero" point in standards for basal metabolism tests submitted by Doctor Askey varies somewhat, depending on the use to which the test is to be put. As is well known, the minimal amount of energy or number of calories sufficient to support the basic metabolism of a resting individual in the postabsorptive state is known as the basal metabolism. The human machine requires energy for its operation; even during rest, either awake or asleep, vital processes continue.

These require fuel; consequently, the first principle of adequate nutrition is to provide the minimum energy required to support this basic resting metabolism.

Clinically, the basal metabolism of an individual is ascertained either for the purpose of supplying an adequate dietary regimen, or for diagnostic purposes—usually to determine the degree of activity of the thyroid gland; although it should be pointed out, parenthetically, that alterations in the activity of other ductless glands may profoundly influence the metabolism.

Doctor Askey's thesis is concerned only with the second of these purposes. As he has concisely pointed out, there are several sources of error inherent in the method of determining the fundamental metabolism, chief among which (excluding technical errors which for the most part are eliminated as the experience of the technician increases) is the varying emotional state of the patient. As a rule, therefore, small variations should be disregarded, unless—and this is important—they occur on the "minus side." It is almost axiomatic that every factor which adversely influences the test tends also to raise the result. In other words, the lower the rate the nearer it approaches actuality. It, therefore, seems obvious that the clinician should only be interested in variations whose increment is greater than at least 10 or 15 per cent, provided the result is above the normal standard.

On the other hand, much smaller changes found in patients with a lowered basal rate may be quite significant. And it is known that the normal standards vary not only with the sex of the individual, but with his or her race, occupation, and the climate in which the person lives. If these factors tend to lower the "zero" point—and they frequently do—5 or 10 per cent in the general normal population of a given locality, the mistakes that may arise in the interpretation of results become obvious.

As Doctor Askey points out, a basal metabolism test should be accepted only as a laboratory aid, and always as of secondary value to clinical impressions; yet if we are to use the test at all, it should be performed as accurately as possible and the results interpreted as correctly as conditions permit.

Commendation is due Doctor Askey for calling attention to a possible source of significant error in determining the basal metabolic rate, a factor which, with little effort, can be entirely eliminated.

MOBILE RIGHT COLON: CLINICAL CONSEQUENCES*

By LEROY BROOKS, M.D.
San Francisco

DISCUSSION by Loren R. Chandler, M.D., San Francisco; John M. Schmoele, M.D., Los Angeles; William L. Bender, M.D., San Francisco.

THIS report is not concerned with the subject of general visceroptosis, but rather with abnormalities of the position and motility of the ascending colon and the clinical consequences.

ANATOMIC BASIS

In the development and rotation of the gastrointestinal tract, the cecum and ascending colon are the last to take their final position. Normally, the ascending colon fuses with the posterior abdominal wall and is broadly attached in the right lumbar region. This rotation and fusion process may vary, from failure of rotation, to abnormal mobility of varying degrees. The right colon may possess a true mesentery or the lower half of the ascending colon may be normally fixed and the upper half abnormally mobile—a condition which causes kinking of the bowel—or the upper part with the hepatic flexure may be normally fixed and the lower part mobile, which may lead to axial rotation of from 90 to 120 degrees, with partial obstruction. Along with the lack of normal fixation, abnormal, congenital or developmental bands are prevalent. Although studies on cadavers show that between 20 and 25 per cent of people have some abnormality of fusion of the right colon, we know that only a relatively small number of these develop symptoms. An explanation of this would probably involve the degree of abnormality, the inherited strength or weakness of the tissue fiber, the relative ability of people to stand pain or discomfort, abnormal relation of adjacent organs from lack of uniform ptosis, stress and strain, occupation, proper or improper nourishment, stability or instability of the autonomic nervous system, the upright position and intestinal stasis.

HOW SYMPTOMS ARE PRODUCED

The writer agrees with Carslaw and Grey that symptoms, when present, are produced by stasis in the right colon, with traction on the narrowly attached mesentery and/or abnormal bands, upsetting the normal physiology of the autonomic nervous system with spasm of the pylorus, ileocecal and other sphincters of Keith, and mechanical and functional obstruction with distention of the involved viscera. An abnormal amount of toxic absorption, as a result of stasis, no doubt also plays a part in the production of general symptoms in some cases.

ONSET OF SYMPTOMS

The onset of symptoms depends upon the onset of stasis which most commonly occurs about the age of puberty. Symptoms may occur in children or in older people, and are more common in

* Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

females than in males, not infrequently beginning after one or more pregnancies. In children the picture is that of the undernourished, poorly developed, dyspeptic, constipated, colicky child of the linear type which is so well known to all. Constipation is a constant symptom.

At first there is discomfort, usually dyspepsia and loss of weight. Later pain occurs and varies in location, which depends upon the degree of abnormal mobility of the right colon and points of attachment of abnormal bands and the viscera mechanically or functionally involved. While the location of the pain or discomfort varies in different patients, the type and location of the pain is remarkably constant in a given patient, but the time and duration of the pain are most erratic. It may be present for one or several days, then mysteriously disappear for a day or more, only to recur exactly in the same place and to be always of the same type. In fact, a most characteristic feature of the history is this erratic "constant inconstancy" of the symptoms. The symptoms are usually worse toward the end of the day, or following strenuous work or exercise. The patient will often be relieved by cathartics and enemas, or upon assuming the reclining position. There may be, and in the worst cases often is, a history of repeated attacks of diarrhea accompanied by an increased amount of pain, beginning in the region of the cecum, but with absence of the usual amount of mucus common in mucous colitis. Stool examination does not reveal any specific cause of the attacks which are due, we believe, to excessive putrefaction and fermentation with typhlitis and diarrhea.

LATER SYMPTOMS AND SIGNS

As time goes on, more weight is lost; the patient becomes nervous, and is often classified as a neurasthenic and drifts from one doctor to another. It is, in general, characteristic of these patients that, after the history and examination have been completed, their conditions do not fit into any of the better-known pathologic entities within the abdomen. Neither do they respond to medical or dietary treatment, as do ulcers, gall-bladder disease, colitis, etc. Not infrequently they lose their appendix, gall-bladder, or ovary, as the result of an honest attempt to give relief. Finally they develop colitis, gall-bladder disease, duodenitis, ulcers, etc., and the picture becomes complicated and the original symptoms are overshadowed by the more constant recognizable ones of the organic changes. While there is only a small percentage of people with abnormal mobility of the right colon who have symptoms, no doubt there are many who go unrecognized or upon whom an erroneous diagnosis of chronic appendicitis, neurasthenia, etc., is made.

The gastric symptoms predominate when the hepatic flexure is not fixed, and the pyloric end of the stomach and duodenum are dragged downward and the load of the heavy right colon is partially borne by the tissues toward the cardiac end of the stomach. This type may have pain in both the right and the left upper quadrant, indigestion, loss of weight, abundance of gaseous

eructations—sometimes to the point of social embarrassment—and nervousness is a common feature.

When abnormal congenital bands are attached to the colon and gall-bladder, one is apt to elicit symptoms referable to this region. Traction through the superior mesentery and right colon arteries may lead to chronic obstruction of the duodenum, attacks of vomiting, headaches, and acute upper abdominal pain (acute duodenitis) lasting from three to five days, often requiring rest in bed and sometimes morphin for relief. There is no muscle-guarding as in gall-bladder disease. In between attacks, the symptoms are those of chronic duodenal ilius. The symptoms differ from ulcers of the stomach or duodenum or gall-bladder disease in the erratic nature and lack of relief by diet and medical regimen. Patients may or may not be relieved by taking food, and usually have given up dieting, as they feel as well when eating one thing as another.

Occasionally, pain in the right lumbar region is a prominent feature. This may vary from discomfort to Dietl's crisis, with the well-known symptoms, and is due to a reno-colic band connecting the ptosed ascending colon with the anterior surface of the kidney, dragging the latter downward. Fixation of such kidneys offers only temporary relief, since the heavy right colon will again drag the kidney downward.

RIGHT LOWER QUADRANT TYPE

The right lower quadrant type is the most common and is met in patients who have more or less normal fusion of the hepatic flexure of the colon, but with lack of fusion of the cecum and a varying amount of the ascending colon. They have right lower quadrant pain, constipation—usually indigestion milder than in the incidences with greater lack of fusion, as cited above. The right lower quadrant pain is dragging or aching in type from overdistention of the cecum, or traction of congenital bands, is not present every day, worse on exercise, and when the constipation is worse, relieved by cathartics, enemata, and rest in bed. In some cases there is superimposed upon this dull right lower quadrant pain, a colicky type of pain which is usually due to a large-mouthed appendix trying to empty itself, or one that contains fecoliths. It is not uncommon for this type to have an acute attack simulating in some respects an attack of acute appendicitis, but differing from acute appendicitis in that the pain usually begins and stays in the right lower quadrant of the abdomen. There may be—but usually there is not—nausea or vomiting. There is lack of elevation of the temperature, lack of an increase in the leukocyte count as seen in acute appendicitis, and there is generally no actual rigidity, but extreme tenderness upon pressure in the right lower quadrant of the abdomen. Operation upon such patients during such an attack, which is often the procedure of wisdom, will reveal a heavy, thickened, grayish, edematous cecum, filled with liquid and gas and with enlarged lymph glands in its mesentery, and an insignificant appendix, the removal

Duodenum or renal	16	
General ptosis	1	
Total	69	

of which will not prevent the patients continuing to have their dull right lower quadrant pain, nor their occasional attack, similar to the one for which they were operated upon.

Physical examination of these patients does not furnish diagnostic aid comparable to that furnished by the history, except to help rule out other better known lesions. The types who have lack of fixation of the hepatic flexure are of the linear type, with narrow, flat, long chest, a small upper and large lower abdomen, with a straight lumbar spine. Those interested in this body type in connection with abnormal mobility of the right colon, are referred to publications by Longyear, Coffey, Goathwaite, and others. Contrary to general opinion, the right lower quadrant type may be met in patients of normal build or of the lateral type.

BILIARY TYPE

In the biliary type, discomfort is usually elicited by pressure over the dilated duodenum. During the examination the duodenum can often be emptied of its liquid and gas contents by pressure of the hand over this viscus, with the patient in the knee-chest position, and the patient has often learned that this position gives relief.

RENAL TYPE

In the renal type the movable kidney can be palpated. The right lower quadrant type complains when pressure is made over that quadrant, and gaseous distention of the cecum is excessive and one can sometimes hear the contents splash or gurgle. The cecum can often be outlined by percussion.

DIAGNOSIS

The x-ray is a valuable aid in determining the abnormal mobility of the right colon, dilatation of the duodenum, spasm of the pylorus and stasis in the cecum, and in helping to rule out other pathology.

The differential diagnosis is made by a process of elimination of the other clinical entities with simulating symptoms. A detailed accurate history properly interpreted is compulsory before arriving at a tentative diagnosis.

Since many of these people are nervous it becomes necessary to determine whether the nervous

TABLE 3.—*Results*

Relieved of symptoms	63	91.3%

Failure	2	2.9%

symptoms are primary or secondary to the loss of weight and run-down condition. This is often difficult and at times impossible. But if the patient had indigestion, loss of weight, pain in the abdomen, constipation, etc., before the onset of insomnia and other nervous symptoms, and particularly if she is annoyed or aggravated by her ill health instead of telling her story with apparent pleasure, the chances are her abdominal trouble is primarily organic due to traction on the mesentery of heavy proximal colon, with upset of the autonomic balance and mental outlook.

It should ever be kept in mind that since an abnormally mobile right colon is so often present without producing any symptoms, it should be incriminated only after all the other better-known pathologic entities have been ruled out by the history, examination, and a thorough exploration of the abdomen at the time of the operation.

PROBABLE EXPLANATION OF SYMPTOMS

The following facts are significant in connection with the hypothesis that the symptoms are caused by traction on the mesentery or developmental bands attached to the parietal peritoneum or adjacent organs, and mechanical stimulation of the sympathetic nerves:

The gastro-intestinal tract has a dual nerve supply with delicately balanced, opposing functions. On the one hand is the sympathetic proper, which comes from the thoracic and upper lumbar cord, and on the other the parasympathetic which is supplied through the vagus and the sacral autonomies. Stimulation of the sympathetic results in a relaxation of the muscles of the gastro-intestinal tract and tends to inhibit peristalsis, but tightens the sphincters. The sphincter at the cardia, the pyloric sphincter, the ileocecal sphincter and probably the other sphincters of Keith's, are caused to contract by stimulation of the sympathetic nerves.

Stimulation of the parasympathetic causes diametrically the opposite effect from that of stimulation of the sympathetic. It is, however, well known among research workers and clinical surgeons that tension on the mesentery or the parietal peritoneum results in a response on the part of the sympathetic nervous system, and not in a response on the part of the parasympathetic.

TABLE 2.—*Sex and Age Incidence*

	Under 10 Yrs.	10-19 Yrs.	20-29 Yrs.	30-39 Yrs.	40-49 Yrs.	Total

Male	3	4	6	3	..	16
Total	5	25	26	11	2	69
Percentage	7.3%	36.2%	37.7%	15.9%	2.9%	100%

During operations under local anesthesia (not spinal) it can often easily be observed that the peristalsis of the intestines is very active. Slight tension on the mesentery or the parietal peritoneum will cause these intestinal movements to instantly cease and the bowel will, within a few seconds, be seen to dilate to twice or three times its original size. This is evidence of a sympathetic response or reflex to the tension on the mesentery, and the amount of tension necessary to demonstrate the above can easily be furnished by the weight of the ptosed, heavy, thickened, liquid-filled, swinging right colon. At operation on one of these patients, one is struck by the weight of the cecum and the first part of the ascending colon when it is lifted out of the abdominal cavity. This traction would not only cause spasm of the pylorus, hyperchlorhydria, and indigestion, but would interfere with peristalsis and favor stasis and, when long-continued, would establish a vicious circle and have a profound effect upon the individual's nervous system and general well-being.

It will be remembered that practically all our water is absorbed from the right half of the colon, and also that normally there occurs antiperistalsis which begins about the middle of the transverse colon and progresses backward to the cecum, a mechanism for retention of the heavy liquid feces until the water has been absorbed.

With an abnormally mobile cecum, with a narrowly attached mesentery or congenital bands attached to the viscera or to the parietal peritoneum, this load must be carried by such structures while the patient is in an upright position. The fact that many of these people are completely relieved of their symptoms during pregnancy, due to the bowel resting upon the plateau of the uterus as it rises out of the pelvis, and the load is no longer carried by tension on the mesentery, is a common observation, worthy of note. We have all seen at operations, many times, the cecum lying upon the bony floor of the pelvis, where ptosis of proximal colon is marked, and the patient having no symptoms relative thereto, because the load rests upon the bony pelvis and is not suspended by the mesentery.

Kantor and his coworkers at the Presbyterian Hospital in New York reviewed the record of 959 gastro-intestinal cases. They discovered cecal stasis in 27 per cent. In the cases of stasis they found that the symptoms of headaches, vomiting, right lower quadrant pain and right lower quadrant tenderness were from one and one-half to over two times as high in the low ceca group as in the normal, or high ceca group. Hirsch's work in 1924 on the cecocolic sphincter is significant, but time is not available to go into details.

Operation for the removal of the appendix following a diagnosis of chronic appendicitis does not give satisfactory results.

A fair average of the reports from our leading clinics would place this operation in the best hands, as a failure in about 50 per cent of the cases. It is not the intent here to carry the impression that all of these failures are due to an abnormally mobile cecum and ascending colon, but there is no doubt that many of them can be explained upon

Fig. 1

Fig. 2

Fig. 1.—The abnormally mobile ascending colon and cecum have been lifted out of the abdomen, revealing the true mesentery (A) with its arches of blood vessels and the opaque, nonvascular false mesentery (B). (After Waugh.)

this basis. Finally, the simple colexy, according to the method of the English surgeon, Waugh, relieves tension on the mesentery and cures a sufficient number of these troublesome patients to warrant its further use until something better is offered.

TECHNIQUE OF OPERATION

Upon opening the abdomen an exploration is made for the more usually recognized pathology. A thorough search for the prevalent abnormal congenital bands is often awarded by positive findings. The most common band is one that extends from the right side of the omentum attached to the ascending colon and to the lumbar region. Other abdominal bands will not be detailed in this paper for lack of space. Any congenital band is dealt with according to indications.

Upon picking up the cecum and ascending colon, one finds that it comes outside of the abdomen. Inspection of the outer side of its true mesentery will reveal a fascial extension drawn out from the lumbar region, and has been called a pseudo-mesentery. This fascial sheet varies in extent with the amount of drag on the lumbar fascia, and in length and thickness with the degree of mobility of the right colon and the age of the patient, respectively. This statement holds, however, only when there is some degree of fixation of the colon at the hepatic flexure.

As illustrated in Figures 1 and 2, this fascia is separated from the true mesentery, and after a space has been made in the lumbar region for the ascending colon the edge of the fascia is sutured to the anterior longitudinal line of the ascending colon. Small and necessary variations in the exact technique will vary in individual cases and with the mechanical acumen of the operator.

RESULTS RECORDED IN THE LITERATURE

In 1920 Waugh reported in detail his results in 180 cases of colexy, according to the method

Fig. 3

Fig. 4

Fig. 3.—The false mesentery has been turned outwards, exposing above the lower pole of the kidney, on the inner side the ureter, and, crossing the quadratus lumborum muscle, the iliohypogastric, ilioinguinal, and external cutaneous nerves. (After Waugh.)

Fig. 4.—The ascending colon and cecum having been rolled into the extraperitoneal space, the cut edge of the false mesentery has been stitched to the anterior longitudinal band. (After Waugh.)

just shown. It was at this time that we first became interested in this subject, and apparently many others were stimulated by the same article, as recently there have occurred in the literature several reports of work which was started about that date. Altogether, to date, Waugh has reported 518 cases with cures between 75 and 80 per cent, improvement in about 12 per cent, and failures in from 8 to 10 per cent.

Carslaw of Glasgow states that he received his stimulus from Waugh's paper and undertook to operate upon any medical failures suffering from ptosis, as a piece of research work. Over a period of seven years he operated upon 242 cases according to the method of Waugh. He reports that he has followed up 239 of these, and either saw them himself or communicated with their family physician, who saw them. He reports a cure in 70.7 per cent of the cases, much improvement in 18.4 per cent, and failures in 10.9 per cent. Among these were many who were suffering from general visceroptosis, and upon whom he operated, and it was in this group that he met with the greatest percentage of failures. Ten of his patients had previously been appendectomized without relief, and were completely cured by the colepexy. His article amounts to a monograph on the subject, and is very well done.

McConnell and Hardeman of Dublin, Ainsworth of Waco, Texas, Quain of Bismark, North Dakota, and others, have reported results similar to the results of Waugh and Carslaw. Houston of Augusta, Georgia, an internist, has, since 1920, had 145 colepexies performed; and while he does not give a percentage of cures or failures in figures, he states that the results are far more satisfactory than the results following plastic operations in gynecology. This certainly coincides with my experience. He further states that it makes it possible for him as a medical man to keep well, and at work after operation, patients who, before operation, would have periodic breakdowns and

have to discontinue their occupation for a rest cure. Twenty of his patients had previously been appendectomized without relief, and were relieved by colon fixation.

AUTHOR'S EXPERIENCE

Of the colon fixations which we have done in the past fourteen years, we have been able to follow sixty-nine patients. A duodenojejunoscopy and fixation were done in three because of the enormously dilated duodenum. A general plastic, consisting of shortening of the gastrohepatic ligament, fixation of the transverse colon through the omentum to the anterior abdominal wall and a right colon fixation was done in one patient with general visceroptosis, who had been bedridden for fifteen months and who has been well now for seven and one-half years, working steadily as a jeweler. Out of the sixty-nine cases, we can report sixty-three who are relieved of the abdominal symptoms of which they complained; four are very much improved and two are failures. The patients placed in the improved group have all been patients who had a very long transverse and descending colon and, while they are relieved of the dragging type of pain in the right side of their abdomen, they still have, at times, abdominal pains which are relieved by enemas. One of the failures was a young girl about seventeen years of age, operated upon for acute appendicitis and who had a gangrenous appendix, and because of continued right-sided chronic aching type of pain, two years later she was reoperated upon and a colon fixation done. She is still constipated, has indigestion, headaches, is of a very nervous type in spite of the fact that she is quite plump, she still complains of a great deal of right-sided abdominal pain. Urological search and other examinations have failed to find the cause of her pain.

Our other failure occurred in a woman about forty-five years of age, who had previously had an ovariectomy, an appendectomy and a cholecystectomy at different operations, and many operations for fissure of the anus. She was of the biliary type, and has marked colitis; and while her medical man maintains that he thinks she has definitely been benefited, she still has many complaints when she talks to me.

We have been mindful all the while that this is a subject upon which one could easily go astray because there are many patients who have abnormal mobility of the right colon who do not have any symptoms whatsoever as a result thereof, and in operating, even though an abnormally mobile cecum and ascending colon were present, and at the time of the operation other pathology found which would explain the patient's symptoms, the colepexy has not been done. There have been several cases with mobile ascending colon in whom a large-mouthed, kinked appendix, containing enteroliths, have been removed and who have come back complaining of a dull aching pain in the right side, and whom we believe would have been relieved had a colepexy been done, although at the time of the operation it was thought that the condition of the appendix was sufficient to explain the symptoms.

The operation is simple, easy to perform, adds only about ten minutes to the operating time, is not destructive—on the contrary, is constructive and is based, I believe, upon sound physiologic principles. It does not increase the number of operations, as these patients are recruited from those (medical failures) whose symptoms cause them to be opened for chronic appendicitis, questionable gall-bladder, ulcers, exploratory, etc.

IN CONCLUSION

The subject is too big to try to cover in a short paper, but, in conclusion, we would like to say, with Houston, that we believe if those who are interested will refer to Waugh's original essay on his 180 cases in the *British Journal of Surgery*, 1920; to McConnell and Hardeman's essay in the same journal, 1924; and again in the same journal of 1928, to Carslaw's long article reporting 242 cases of colepepy as studied in Glasgow; and further if he will familiarize himself with the mass of literature on the subject in the light of physiology, he will inevitably come to the conclusion that some of the most troublesome patients fall in this group, and that many of them can be cured by fixing the ascending colon in its normal position.

2000 Van Ness Avenue.

DISCUSSION

LOREN R. CHANDLER, M. D. (Stanford University Hospital, San Francisco).—Doctor Brooks has reviewed excellently the clinical aspects of mobile cecum, and his experience with the Waugh operation shows a high percentage of cures. However, I disagree sharply with him on his interpretation of how symptoms are produced, and upon the treatment indicated to relieve these patients of their complaints.

The abnormal bands referred to undoubtedly are congenital. They are present in a large number of infants and new-born, and have such a regularity in their position that it seems unlikely that they could be produced so exactly and frequently by intra-abdominal inflammation. The bands are always attached to the anterior longitudinal band of the ascending colon, a short distance below the hepatic flexure, and extend laterally and upward to the parietal peritoneum below the lower pole of the right kidney. They are lateral and anterior to the true peritoneal mesentery of the colon. These bands also may extend from these two limits to other points, involving the duodenum and gall-bladder and, in some cases, the visceral attachment of the band extends cephalad onto the terminal portion of the small bowel. But no matter what else is involved, the attachment to the colon is to the anterior longitudinal band. Inasmuch as the parietal attachment is above and behind the visceral attachment, these bands do not pull on the mesentery of the colon or small bowel, but tend to pull the point of attachment on the colon backward, and rotate it laterally. This leaves the cecum and that portion of the ascending colon proximal to the point of fixation unusually free and mobile.

Many persons possess these bands, but do not have symptoms. Careful observation reveals the fact that when these bands are short the ascending colon is partially obstructed and rotated laterally at the point of attachment of the band. Patients with this condition have the symptoms so well described by Doctor Brooks and others. When these bands are long and there is no obstruction or rotation (and this condition is found a great many times), the patients do not have abdominal symptoms. The partial obstruction produces stasis and must interfere with normal physiology; but I have never been convinced that "traction on the narrowly attached mesentery and/or abnormal bands upsets the normal physiology of the autonomic nervous system"—in such a way as to cause this type of intestinal complaint.

Inasmuch as the symptoms are due to obstruction, the treatment is to relieve the obstruction. This is done by sectioning the abnormal band at or near its attachment to the parietal peritoneum. This relieves the obstruction promptly and, I believe, permanently. The Waugh operation separates the attachments of the band, which I believe produces the cure, but goes further in that the abnormally mobile cecum and lower part, of the ascending colon are sutured to the fascia of the posterior abdominal wall. This part of the Waugh operation is unnecessary to effect a cure.

Although I am not aware of any definite symptom-complex or syndrome in these patients, I agree with Doctor Brooks that this condition is a very definite entity which can be cured by operation.

✽

JOHN M. SCHMOELE, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Brooks's paper deserves intensive study by all clinicians and surgeons. The problem of the mobile right colon, associated with congenital bands of various types and anatomical positions, is still somewhat of an enigma to most of us; yet, after studying the observations of the author, Waugh, Rea Smith, McConnell, Carslaw, and others, one must feel that this solution is at least in sight.

I have had the opportunity to be associated during the past decade with the late Dr. Rea Smith, who carried on a great amount of practical work in this field, paying especial attention to the relationship between chronic arthritis and toxic intestinal absorption, resulting from congenital malposition and bands blocking the right colon. A right-sided colectomy was performed with the Lane short circuit in the beginning. This series included over one hundred cases. The Waugh operation was done later, but during the past seven years the opaque avascular false mesentery or band was simply excised and the bowel supported externally by properly fitting abdominal supports.

The chemistry and physiology of the right bowel following any type of reconstructive surgery must be considered if relief of symptoms are to be expected with relative rapidity. The intestinal flora should be studied, peristalsis stimulated, and rigid attention paid to diet.

Doctor Brooks, for want of space, has not stressed sufficiently the importance of detailed roentgenologic studies in making the diagnosis of abnormalities of the right colon. (I refer to a technique developed by Taylor. (*Journal of Bone and Joint Surgery*, Vol. 10, No. 1, pp. 62-68, January, 1928).)

Our clinical results have been tabulated primarily on the basis of symptomatic relief of chronic arthritis rather than the relief of gastro-intestinal symptoms, which we have considered secondarily. It suffices at this time to say that our results have been clinically satisfactory, although our experience with the Waugh operation does not warrant an authoritative criticism.

✽

WILLIAM L. BENDER, M. D. (384 Post Street, San Francisco).—Mechanical abnormalities of the colon are frequent, in the distal as well as the proximal portion. For some time I have been interested in the symptoms due to unusually long or redundant sigmoid colon. Opinions differ as to the acquired or congenital status of this condition. Therapeutically, one should bear in mind that obstruction or stagnation distally may influence the result of operation to relieve the condition described by Doctor Brooks, through back pressure. Since developmental anomalies tend to be multiple, the gastro-intestinal examination should be cognizant of others, such as diverticula, including Meckel's, and diaphragmatic abnormalities. On the whole, the reported results of colepepy are good, and unquestionably the procedure deserves the emphasis Doctor Brooks places on it.

✽

DOCTOR BROOKS (Closing).—I wish to thank Doctors Chandler, Schmoele, and Bender for their discussion of this paper. I am in entire agreement with Doctor Chandler in reference to the band that he describes as being congenital. He is also correct in his description of its attachment or probable attachment. It is accepted that this band represents a lateral extension of the omentum. In fact, its blood supply is continuous with that of the

omentum, and, so far as I know, no one who is informed any longer contends that it is of inflammatory origin. Moreover, the band often only extends to the ascending colon and does not cross this portion of the gut, and is not necessarily attached in the lumbar region. The band may or may not be responsible for partial obstruction, and may or may not, therefore, cause any symptoms.

I do wish, however, to take issue with Doctor Chandler when he infers that this particular band is necessary for the production of the chain of symptoms outlined in this paper, for the excellent reason that the majority of the patients under discussion here, and in the experience of others, did not have this particular band, and did have the symptoms outlined and were relieved by operation. I am convinced that the right lower quadrant discomfort or right lower quadrant pain is due to a distention of the cecum, whether the distention is caused by partial mechanical obstruction or by functional stasis without mechanical obstruction, except that, clinically, with mechanical obstruction the symptoms are apt to be more constant than the variable symptoms in the cases with functional stasis.

I did not state in this paper that this congenital band pulled on the mesentery. The fact is that some congenital bands that take part in disturbing the autonomic nervous system do so by pulling on their attachment to the parietal peritoneum. A slight pull on the parietal peritoneum through a congenital band, or a pull on the mesentery by the weight of a filled cecum, does definitely disturb the sympathetic part of the autonomic nervous system. This fact can be definitely and easily demonstrated at operation under local anesthesia, and confirmed by irrefutable evidence presented in all standard textbooks of physiology. This paper was meant primarily to deal with the chain of symptoms or clinical entity based, in my opinion, upon morbid or pathologic physiology and not so much as in the usual surgical lesions on deadhouse pathology.

I believe there is a definite relationship between stagnation of the cecum with absorption of bacteria with increased virulence and progressive arthritis in people with advancing years. I am indebted to Doctor Schmoele for bringing out this point. Time and space did not permit of the discussion of this aspect of the subject at this time. However, it is propitious to say here that if there is a definite relationship between cecal stasis and arthritis, it should be important to relieve the stasis of the cecum by whatever means necessary and prevent or slow down the development of the multiple arthritis.

Likewise, Doctor Bender brings up an important point relative to congenital abnormalities often being multiple, all of which may have a definite significance in any given case; but a general discussion of these complications to right mobile colon could not be crowded into the time allotted to this paper.

CONGENITAL OCCLUSION OF THE SMALL INTESTINE*

By JOHN HOMER WOOLSEY, M.D.
Woodland

DISCUSSION by E. Eric Larson, M.D., Los Angeles; William J. Norris, M.D., Los Angeles; Edwin M. Taylor, M.D., Oakland.

CONGENITAL occlusion of the small intestine occurs from both intrinsic and extrinsic causes; in single and multiple forms; and chiefly in the duodenal and ileal regions. Its frequency merits attention. It can be diagnosed and is amenable to surgical correction. Newer ideas of stool examination and proved methods of roentgen-ray study aid tremendously in its recognition, location,

and degree of occlusion. Proved and clever methods in technique aid greatly in the operative treatment.

ETIOLOGY

One would think that occlusion would occur at the site of junction of the embryologic portions of the primary gastro-intestinal tract, such as the junction of the fore- and midgut, and the mid- and hind-gut; but this is not so. Also the often-quoted remark of Bland Sutton of 1889, "always in the situation of embryological events," is not strictly true. The occlusion occurs from both intrinsic and extrinsic causes, and these causes play a part in the location of the occlusion.

Intrinsic Causes.—The intrinsic, as recognized today, was described in 1900 by Tandler¹ and more completely in 1907 by Forsner,² a Swedish anatomist. They observed that up to the fifth week of fetal life the small intestine presents a well-defined lumen lined with epithelium; that these epithelial cells rapidly proliferate and obliterate the lumen by epithelial conrescences. By the twelfth week of fetal life these conrescences break down into a liquid state, forming vacuoles which in turn coalesce and reestablish the lumen. If, on the contrary, some interference in development occurs during this period, an atresia or a stenosis may result. Forsner divides the mal-developments into three groups, namely, Group 1, in which a small diaphragm of epithelial cells, either complete or incomplete, occurs across the lumen, thereby giving a complete or partial occlusion; Group 2, in which there are two blind ends of intestine joined by an intervening cord, known as an atresia; and Group 3, in which there are two blind ends of the intestine absolutely unconnected—also an atresia.

Extrinsic Causes.—The extrinsic causes are those due to a sclerosis of the blood vessels to a local area with a resultant lack of development because of insufficient blood supply; to mal-development of the vitello-intestinal duct, in that if atrophy of this embryologic tract goes on to excess it absorbs some of the primitive bowel, giving either a stenosis or an atresia; and to faulty rotation of the intestine with compression of the blood supply and a secondary loss of development.

Faulty rotation is considered to be a cause of abnormal conditions in the lower ileum. Faulty rotation may present a disturbance at many levels due to compression of a local blood supply from a constricting fibrous band, from overfusion of a mesentery, or from a volvulus. The normal embryologic process of development and rotation of the small intestine is somewhat as follows: After the fifth week of fetal life, the liver and other visceral organs grow faster than the abdominal cavity, and the midgut is forced into the base of the umbilical cord. By the tenth week the midgut begins its return, with the duodenal, jejunal and upper ileal segments being first. As they return they pass in sequence from the right to the left behind the superior mesenteric artery. This leaves, as the last loop to return, the lower ileum, cecum,

* From the Surgical Service of the Woodland Clinic.

Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

the ascending colon, and a portion of the transverse colon. In this final loop the apex is formed by the vitello-intestinal duct, later known, when it persists in a blind pouch, as Meckel's diverticulum. As the final loop returns to the abdominal cavity, it crosses from left to right in front of the superior mesenteric artery, and its mesentery becomes fused with the posterior parietal peritoneum, thereby giving the firm attachment of the right-sided portion of the large intestine and the oblique left to right of the lower small intestine. An arrest of development at any stage is a potential volvulus, hernia, or constriction of the blood supply by pressure from faulty rotation or by fibrous bands.

INCIDENCE

Occlusion of the small intestine is most often single, but occurs sufficiently multiple—15 to 19 per cent, to demand a thorough inspection of the entire intestinal tract at operation. They are most common in the duodenum, more especially in the region of the ampulla, and in the ileum at the embryologic site of the vitello-intestinal duct. They are quite common at the ileocecal valve region, and do occasionally occur in the jejunal and upper ileal positions.

A summary of reports of a few series of collected cases shows that approximately 44 per cent occur in the duodenal region, 18 per cent in the jejunal region, 37 per cent in the ileal region, and 19 per cent were multiple.

In the duodenal area, occlusions occur chiefly in the ampullary region and are about equally divided as to location above and below the ampulla.

DIAGNOSIS

The clinical findings depend upon the location and the degree of the occlusion. Ordinarily the symptoms occur in the first six days, and begin in the first twenty-four hours. An atresia will give a prompt onset, but a stenosis may be so mild as to allow the child to retain the majority of the food and go on to even adult life before sufficient disturbance occurs to demand surgical investigation.

Regurgitation or vomiting, at times projectile in character, is the first symptom of importance. As a rule, gastric distention is present, and deep peristaltic waves are often observable. If the occlusion is in the ileal region, a more general distention will occur. Loss of weight and dehydration are other signs that follow.

One should always look for the passage of meconium. If continued vomiting occurs, microscopic examination, as described by Farber⁹ in 1933, should be made. Meconium appears in the intestinal tract at about the third month of fetal life. It is composed of the amniotic fluid, and its contents are derived from the skin of the fetus, namely, vernix caseosa, lanugo hair and cornified epithelial cells, also bile, pancreatic secretion, intestinal secretion, and desquamated intestinal epithelium. The cornified epithelial cells have, as their only source, the skin of the fetus, and if a

microscopic study of the meconium shows an absence of these cells, there is somewhere between the mouth and the anus a complete occlusion of the gastro-intestinal tract. Farber suggests the following routine for this examination:

1. Make a thin smear of meconium on a glass slide.
2. Place the slide, either immediately or when dry, in a dish containing ether for one to five minutes, until fatty substances disappear.
3. Dry in air for a few seconds.
4. Stain for one minute with Sterling's gentian violet (or better, methyl violet).
5. Wash in running water.
6. Decolorize with acid alcohol.
7. Dry and examine.

He states that the cornified cells stain blue, while all other cells are decolorized.

Roentgen examination, both with and without contrast medium, is of great assistance, and in fact may make the diagnosis. A plain plate of the abdomen will often outline the point of occlusion by the presence of gas to a certain point, in contrast to absence of gas generally. The use of contrast medium, we believe, is not fraught with danger, provided one gives a minimum amount. The x-ray findings without contrast medium are more valuable in an atresia, but with a contrast medium a stenosis is more likely to be demonstrated. An exact diagnosis is most important in directing the treatment, for it is desirable to avoid all unnecessary exposure in an abdominal exploration and to perform quickly whatever surgical procedure is indicated. The exact location of the occlusion, and the differentiation between an atresia and a stenosis directs the surgeon to the site of the trouble and give him definite information as to where he should or can make the new anastomosis.

Differential Diagnosis.—The differential diagnosis lies in distinguishing chiefly between the more common obstruction of a congenital hypertrophied pyloric muscle, which occurs usually after the twelfth day rather than during the first six days; an obstruction of the esophagus, demonstrable by x-ray; an occlusion of the large intestine, demonstrable by the degree of general abdominal distention and x-ray studies; an imperforate anus, diagnosed by physical examination; and vomiting from a so-called functional cause, which is usually controlled by atropin and thick feeding.

It is true that intestinal occlusion is rare; but with vomiting in the newborn it is always mandatory to prove, before the little patient reaches the stage of exhaustion from starvation and dehydration, that it is not on a mechanical basis that may be corrected.

TREATMENT

Early diagnosis and prompt treatment is of vital importance. Primarily the patient, who as a rule is somewhat dehydrated, should first be supported with adequate amounts of subcutaneous fluids.

TECHNIQUE

Anesthesia should be either local infiltration, supplemented by a small amount of ether by open

mask during the intra-abdominal surgery; or ether during the entire procedure.

An upper or mid-right rectus incision gives the best exposure, and may be enlarged as desired. The more exact the diagnosis the more direct the treatment may be; but under any circumstances a rapid palpatory exploration of the sigmoid and of the transverse and ascending colon should be made. The small intestine should then be inspected visually throughout its entire extent for the presence of multiple occlusions.

In any of the occlusions, except those occurring by faulty rotation, an entero-enterostomy or a gastrojejunostomy when indicated, is the procedure of choice. In the past the majority of ileal occlusions have been treated by an enterostomy, and almost universally the patients have died. It is believed that the deaths were, however, due in part to late surgery and to the failure to employ parenteral fluids. If the occlusion is in the duodenal or duodenojejunal region and is complete, a duodenojejunostomy is the procedure of choice; and even if incomplete, this treatment is probably the more satisfactory. Frequently a gastrojejunostomy performed for the high and complete occlusions has been followed by continued, though modified distress, and later a duodenojejunostomy has been necessary to give complete relief. A gastro-jejunostomy, on the other hand, is far easier to do, will as a rule tide the patient over to a safer age for surgery, and in the stenotic form is in the majority of instances just as satisfactory. Occlusions from the jejunum to the colon are best treated by entero-enterostomy.

Technique.—The technique of these operative procedures is very important. Open anastomosis without clamps is the procedure recommended. The two portions of the gastro-intestinal tract to be anastomosed are brought into apposition. A black silk suture is taken at either end through both portions and held taut as guy supports by the assistant. All other viscera are replaced if necessary into the abdominal cavity and securely held there by moist gauze sponges, with only the portion to be anastomosed exposed. For the outer layer, interrupted silk sutures are employed, and for the inner a running suture of double 0 plain catgut intestinal suture, swedged on the atraumatic needle. This method gives definite knowledge that the anastomosis is patent; avoids too much turning in of the anastomosed edges; gives adequate support until healing is completed; causes the least trauma to the tissues; and prevents shock by a minimum amount of exposure.

Always in an atresia, and occasionally in a stenosis, the intestine below the site of occlusion is collapsed. The size of the lumen is such as to make one wonder if it will ever function. The author has recently noted a similar appearance in an adult where the ileum, unused for two years, was collapsed to a ribbon appearance, and yet was distensible to a seven-centimeter diameter. In 1904, Clogg suggested that, before proceeding with the anastomosis, the collapsed bowel be distended with fluid or air. In 1933, Ladd suggested

the use of a catheter inserted in the lower collapsed segment and the suturing of the anastomosis over this. The distention of the collapsed loop with sterile water or normal salt solution not only enlarges the bowel for the surgery and demonstrates its patency, but provides additional fluid which is necessary and can be promptly absorbed.

The subject of the handling of an obstruction caused by faulty rotation will be discussed in other papers to be read at this meeting. In addition, an excellent article by Ladd in 1933 is recommended.

Prognosis.—The prognosis for the successful treatment of occlusion of the small intestine should not be judged upon the past experiences of the profession. Proper preparation with fluids, early and definite diagnosis, atraumatic technique, and parenteral fluids postoperatively, as well as an intelligent use of breast milk or formula, should raise the percentage of successfully treated patients. The first successful cases were reported in 1911 by Fockens, a Dutch surgeon; in 1916 by Ernst, an English surgeon; and of especial interest to us, a case in 1916 by Alanson Weeks of San Francisco.

REPORT OF CASE

Another successful case is hereby reported.

W. C. H. No. 39072. A male infant from the third postnatal day regurgitated and later vomited much of the food taken, and bile-stained fluid. By the twelfth day a loss of twenty-five ounces in weight had occurred. Meconium had been passed. Varied formulas and atropin had been employed. Physical examination demonstrated a laxness of tissues from weight loss and moderate dehydration, a slightly distended stomach, marked gastric peristaltic waves from left to right, and a patent anus. A tentative diagnosis of congenital hypertrophy of the pylorus was made and an x-ray investigation was begun.

Barium sulphate was given by mouth and there was demonstrated a marked dilatation of the stomach and hyperactive peristalsis with the waves passing through the antrum, a patent pylorus, and a hugely dilated duodenum, ending abruptly in the fourth portion. At the end of one hour a very narrow lumen at the point of obstruction was demonstrable in the film. A diagnosis of partial occlusion at the duodenojejunal junction was made.

After preparation with parenteral fluids, a celiotomy by right rectus incision was made. Anesthesia was obtained by local infiltration until the abdominal cavity was opened and then a small amount of ether on the open mask was employed. The operative findings were as follows: The stomach, and especially the pyloric muscle, were entirely normal in size; the intestines were in their normal positions; the duodenum was dilated to eight times normal, approximately 4 centimeters in diameter; the jejunum and ileum were extremely small, approximately .5 centimeter in diameter and of even caliber throughout; and the large intestine visible in the upper extent, and palpated in the lower extent, was entirely complete and measured approximately .75 centimeter in diameter. The site of the occlusion was not seen, as it lay behind the stomach.

Since there was sufficient opening to allow the digestive juices of the duodenal area to pass down their normal course, and because of the easier procedure, a posterior isoperistaltic gastrojejunostomy was performed according to the method and technique previously described.

Parenteral fluids were given for the first two days postoperatively, and formula was fed as for a congenital pyloric stenosis. During the first twenty-four hours the infant retained 50 per cent of the intake, and all thereafter. At operation the weight was six pounds, and on the seventeenth day, when discharged from the hospital, the weight was eight pounds five ounces. He has never had any further abdominal distress, has been normal in

every respect, and weighed twelve and one-half pounds at three months. An x-ray examination with barium sulphate demonstrated that the stomach empties at a normal rate by the gastrojejunostomy stoma. No barium was observed to pass through the pylorus and duodenum.

CONCLUSIONS

Congenital occlusion of the small intestine is caused by intrinsic and extrinsic embryologic maldevelopments. It presents its symptoms in the first six days of life. Stool examination and roentgen-ray examination may demonstrate important findings. It may occur in multiple form, and it is amenable to treatment. The treatment consists of the intelligent use of parenteral fluids pre- and postoperatively; thorough abdominal exploration; the employ of atraumatic technique; and an anastomosis rather than an enterostomy.

A case of congenital partial occlusion of the small intestine at the duodenojejunal area, successfully treated, is reported.

DISCUSSION

E. ERIC LARSON, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Woolsey has presented to us one of the interesting problems relative to the surgery of infants.

Not many general surgeons have the opportunity of seeing such an unusual problem nor treating such a patient. His report of a successfully treated patient with stenosis high in the gastro-intestinal tract is most commendable.

I recently treated, unsuccessfully, an infant with atresia situated high in the ileum. There was interposed a flat transparent ribbon, three centimeters in length. I had never seen such a condition, and can assure you that the technical difficulties incident to short-circuiting a distended loop to an unused loop distal to the atresia was most trying. My little patient died, and an autopsy was refused.

Should I ever encounter such a problem again, the author's suggestions relative to diagnosis and preoperative and postoperative care, would be scrupulously heeded. The distention of the distal intestinal loop with saline solution, to insure fluid to the patient and more careful approximation of the enterostomy openings with the atraumatic suture, would be done. I remember very clearly the small apertures left around each suture puncture in the distal loop, and that I felt certain that leakage would endanger my patient's life, which it undoubtedly did.

Doctor Woolsey further calls attention to the high percentage of multiple lesions. A successful operation for the defect, with the failure to recognize other similar lesion, would be gross negligence. It is mandatory that we surgeons operating on infants must know embryology and the usual defects that may occur. The examination, recognition and repair of these defects must be done with the least trauma possible.

✱

WILLIAM J. NORRIS, M. D. (1136 West Sixth Street, Los Angeles).—The entire intestine may be absent or shortened, but not lengthened. In rare cases a fistula may

communicate with the abdominal wall. This may be a helpful factor in tiding the case over until a more suitable time for operation.

My only experience with such a case was an infant, two weeks or more premature, who entered the hospital when three days of age, weighing four pounds and ten ounces. Since birth there had been no bowel movement. The infant had repeatedly regurgitated dark-colored and bile-stained material. Dehydration was marked, and the patient was moderately jaundiced. Rectal examination was normal. X-ray examination showed the presence of an obstruction in the first portion of the jejunum.

Fluids were supplied freely subcutaneously for twenty-four hours before operation. An attempt was then made to wash out the barium which had been given by mouth.

An upper rectus incision was made. The jejunum, about six inches from the ligament of Trietz, was found to end in a fibrous cord. This cord was not attached to the distal portion of the jejunum, which was found as a blind pouch adjacent to the free end of the fibrous cord. The stomach, duodenum, and first six inches of the jejunum were greatly dilated, thickened, and filled with secretion and barium. The distal end of the jejunum was approximately one-half centimeter in diameter.

Had I read Doctor Woolsey's paper before the operation, I would have tried to do an anastomosis. Instead, a large catheter was inserted into the proximal end of the jejunum, and a small catheter into the distal end of the jejunum. These were brought out of the upper end of the abdominal incision. The hope was to allow an opportunity for getting rid of the barium in the stomach, and for the child's general condition to improve.

For two days the patient's condition seemed remarkably good. It then grew worse. The infant expired on the fifth postoperative day.

At postmortem a localized fibrinopurulent exudate was found around the site from which the tubes emerged. The average diameter of the duodenum was two centimeters and of the small intestine and colon, eight-tenths of a centimeter.

Dr. Frank Matthews of New York City kept alive, for one year, a patient with atresia of the terminal ileum by allowing the terminal ileum to drain through the abdominal wall.

Dr. J. Norton Nichols of Los Angeles cared for twins with atresia of the terminal ileum.

May I stress particularly the method of diagnosing complete obstruction mentioned by the author and described so ably in the article to which he referred?

Had a microscopic examination of the feces in my own case been made before the barium mixture had been given, I feel sure that the complication of so much material in the stomach and duodenum would have been avoided.

✱

EDWIN M. TAYLOR, M. D. (230 Grand Avenue, Oakland).—As Doctor Woolsey has pointed out, congenital occlusion of the intestinal tract may be in many locations, due to the many causes stated.

Early diagnosis, the proper preoperative preparation of the patient, and early surgery, are of paramount importance. As we rarely find the same condition present in any two patients, what is to be done must be left to the judgment of the surgeon.

Surgery in the new-born is hazardous, so the least difficult procedures are the method of choice. The fact that anomalies are often multiple must always be kept in mind by the surgeon.

May I present the summary of a case with the autopsy report of Dr. Paul Michaels from the Children's Hospital of Oakland?

J. C., four days old. Had been vomiting for three days. Passed some meconium after birth. At surgery a distended small bowel down to a Mechel's diverticulum was found; bowel below very small. Catheter was placed in Mechel's diverticulum. The patient died five weeks later.

Autopsy: Entire colon atretic, also terminal 18 centimeters of ileum (size .75 to 1 centimeter in diameter). The remaining proximal ileum distended. Diverticulum 30 centimeters in length. The distal end was free. There was no peritonitis and no other congenital anomalies.

SINUS DISEASES: THE USE OF ROENTGEN RAY IN THEIR DIAGNOSES*

By ORRIE E. GHRIST, M.D.
Glendale

DISCUSSION by Dean E. Godwin, M.D., Long Beach;
Harold A. Fletcher, M.D., San Francisco; Charles E.
Futch, M.D., Los Angeles.

HISTORY

IN passing currents from one electric pole to another, it is probable that William Morgan, in 1785, produced the first x-ray, but he certainly was not cognizant of the fact.

The first to recognize that he was dealing with these rays was William Konrad Roentgen of Würzburg, Bavaria. In 1895 this investigator was doing extensive experimental work on the passage of electric current within an evacuated tube. He first noted a strange phenomenon: in a dark room with the tube covered with light opaque material, passage of current within the tube would cause a platino barium cyanid screen nine feet away to fluoresce. During these experiments, one day he was called quickly out of the room. He happened to lay this tube on a book, which book contained a large key under which lay a photographic plate (we know now that in the older type of tubes x-rays were emitted for a time after the current was turned off). He later took a hike, during which he used this film to take a picture. On developing it he noted the outline of this key. He repeated the experiment, and again found the outline, and realized he was dealing with some ray, invisible to the naked eye, and capable of penetrating matter which was opaque to the ordinary light rays.

Because he did not recognize this ray he called it "X" ray. He later laid his hand on a plate and was the first to demonstrate bony shadows on an x-ray plate. He was also the first to show the shadows on a fluorescent screen. It is noteworthy that within a year it was being used in medicine in many places in Europe and America. Four days after its introduction in the United States a bullet in the calf of a man's leg was located.

Sheir, in 1897 (only two years after its discovery), was the first rhinologist to demonstrate that a sinus, which appeared flat on an x-ray plate, contained pus.

PROPERTIES OF ROENTGEN RAYS

Some of the interesting things about roentgen rays are as follows:

If we consider them in relation to the visible spectrum (8000 Angstrom units for red to 4000 Angstrom units for violet), we find they are of much shorter wave length (1000 Angstrom units to 0.06 Angstrom unit), and are to be located in the electromagnetic spectrum far out beyond the violet and ultra-violet rays.

They travel at the speed of light (186,000 miles per second).

They cannot be deflected by a magnet.

It was thought that they could neither be reflected nor refracted, but we now know they can be diffracted and reflected by certain crystals. Seigbahn has obtained a spectrum of x-rays, and it is on this work that the science of crystal analysis is based.

They have certain biologic effects. Depending on the amount of absorption by the cells, they will cause either stimulation, retardation in growth, or complete destruction.

They ionize gases.

Chemically, they cause certain actions: for example, they cause iodine to be freed from iodoform in chloroform.

Those properties which are of especial importance to physicians are:

1. They cause a fluorescence of a platino barium cyanid screen.

2. They affect photographic plates exactly like light rays.

3. They penetrate matter which is opaque to ordinary light, and they are inhibited from penetrating this matter in direct ratio as to its atomic weight.

This latter characteristic is of special importance because, even though x-rays do spell mystery to the layman, a harvest for the charlatan, and a glowing story for the x-ray salesman, to us they are only showing on a photographic film the differentiations in density of the parts x-rayed. This, above all points, should not be lost sight of.

APPARATUS

There are a number of different head-rests used for holding the head and getting the proper angles. No matter what type you use, there are three essentials:

(a) The head must be held exactly in the mid-line, *i. e.*, in the posterior anterior position; the head must be exactly centered in a vertical line, and the x-ray target must be exactly above this center line.

(b) The glabella-mento line must form a definite angle with the horizontal.

(c) The head must be absolutely still while the view is taken. (Check this by noting if the cancellar bone of the jaw around the teeth, etc., stands out clearly.)

We use a head-rest which Dr. D. M. Ghrist worked out a number of years ago. In our experience, it meets all three of the above requirements and can be used either with or without a Potter-Bucky diaphragm.

The nose fits into an opening in a bakelite plate. This fixes the glabella-mento line. The angle at which this plate rests can be read off at the side on an angle meter. The bar which screws the two bakelite side head holders together is a solid bar clear across, fixed at the mid-point, with threads from both sides, progressing toward the center. Thus, when this is screwed up, the head is fixed in the exact mid-line.

NOMENCLATURE

The nomenclature which eye, ear, nose, and throat specialists and the roentgenologists have in

* Read before the Eye, Ear, Nose and Throat Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

common is as a rule easily understood, but there is one thing which we should bear in mind, namely, that in describing the position in which a film has been taken the roentgenologist uses such expressions as posterior anterior (or P. A.), etc.

The first in this case, the "P," means that that part is nearest the tube, and the last in this case, "A," is next to the film. In asking the roentgenologist to take certain views, this point should be kept in mind, for he is able to get the best detail in the part nearest the film.

PENETRATION

The first thing to notice about an x-ray film is whether or not it has been correctly exposed, overexposed, or underexposed. This can be told at a glance. Definitely underexposed pictures are very weak and bleached out. One can see that not enough of the x-rays have gotten to the film. Definitely overexposed pictures give a slaty appearance. If either of these two latter characteristics are noted, little or no exact information as to the status of the sinuses can be obtained from reading the films.

FUNDAMENTAL SETTINGS

There are many variations as to the settings chosen by the different roentgenologists. Nowadays so many different schools are turning out x-ray technicians that it is essential for each of us to choose definite settings with which we may become very familiar, and we should know these positions well enough to ask the technician for them. As for example:

"I wish a sterio P. A. (anterior part or face next to the film) of the sinuses at the 40-degree angle, or the 23-degree angle."

It is, of course, preferable merely to say to an expert roentgenologist, "Please make a thorough sinus study"; but even then when one sees the pictures and reads the report, one must have some concept as to their angles and positions.

All settings should be in sterio, except for Granger's "G" line.

You can check the setting used in the posterior anterior positions by noting where the petrous portions of the temporal bones cut across the film.

POSITION.—Views can be taken in either the lying or upright position. In the upright position, if a sinus is partially filled with fluid of low enough surface tension, Claus has demonstrated a concave line. If this line fails to shift when the head is tilted, the sinus content is likely to be mucopurulent. Convex lines are generally polypi.

The settings which seem to get the best results in sinus studies are the following:

The Forty-Degree Angle.—Here we note the petrous bones are below the lower floor of the antrums. This position gives a good view of the antrums (except their floors), a fair view of the frontals, ethmoid areas, and if the proper type of a wooden block is used to hold the tongue down and the mouth open, a third shift of the tube gives a good view of the sphenoid cells in the open mouth.

The Twenty-Three-Degree Angle.—Here the petrous portion of the mastoids go through part

of the antrums. This gives a better view of the frontals especially.

The Seventeen-Degree Angle Below the Horizontal.—This is Granger's view, and is taken to study especially Granger's "G" line of the sphenoids. Here we also get a good view of the posterior ethmoids, and sometimes obtain information on the anterior ethmoids. This view must be accurate. The head must be carefully centered, and the resultant view will be correct only if the petrous bones pass exactly through the center of the orbits.

Verticomenal View.—This view is used very frequently in studying the sphenoids. It gives information especially as to their lateral extensions.

Lateral View.—This view in sterio often shows quite well the condition of the ethmoids, the anterior posterior limit of the sphenoids and any thickening of the floor of the frontals. Here also we especially should notice how thick the skull is, because, of course, the thicker the skull the less intrasinus detail we expect to get in our other views.

Of the above views, we use routinely the sterio of the 40-degree angle, the Granger "G" line and a sterio lateral, using the other views only as indicated.

EFFECTS DIFFERENT PATHOLOGIC PROCESSES HAVE ON ROENTGEN RAYS

In checking the changes to be noted on x-ray films, one should look for:

(a) Comparative cloudiness: for this comparison we use the inner wall of the orbit. Practically speaking, the inner wall of the orbit gives the same density as the inner portion of the normal sinus.

(b) Changes along the sinus walls, *i. e.*, changes in the thickness of the mucous membrane, how sharp the sinus walls stand out, and whether or not they are partially or totally eroded.

The pathology in the sinuses manifests itself on the x-ray films more or less clearly in direct ratio as to the amount the tissues and spaces are changed in their specific gravity.

Sinuses of Unequal Size.—The smaller shows more dense than the larger.

Edema, or water logging, as we see it in acute disease, gives a markedly fuzzy appearance; and when in the mucous membrane also causes a marked blurring of the distinctness of the sinus wall outline. This is especially noted in the posterior anterior views.

Fluids or Pus.—Make the whole sinus look generally more opaque (the higher the specific gravity of the contents the more opaque they appear). At times a fluid line is demonstrable.

Hypertrophies of the Mucous Membrane.—Shows as a thickening inside the sinus walls. As this condition becomes more chronic, and as a certain amount of osteitis progresses, the bony walls become more sharply outlined. As this further progresses, the outline becomes sharper and sharper until the bone is sometimes eroded. Polyps sometimes reveal their outline in these films. (Law.)

Cysts.—Show an increased density and a rounded and smooth outline.

Osteomyelitis.—The important thing to be remembered here is that the x-rays do not, as a rule, show changes in the structure of bone for from eight to twenty-one days after the disease process starts. This should be borne in mind when looking at mastoids; for although one may see the fuzziness of the edema, or general haziness throughout the bone, from pus or fluid, one does not expect to see changes in the structure of the bone until after the eighth to the twenty-first day. As Doctor Beck once told us in discussing osteomyelitis of the skull, "the disease is at least ten days ahead of your x-ray pictures."

New Growths.—How well do we or do we not see them depends on their effect on the bone. Those new growths which are of a bony character and take on calcium, are, of course, very readily discerned. Carcinomas show only from their effect in bony destruction. Their characteristics are that they show cloudiness of the sinus or sinuses, tend to destroy bony walls, and are much more extensive than you would expect from your x-ray findings.

In applying the aforementioned to a sinus (the antrum for example), we find:

1. Normal sinus: Sharp wall outline; no haziness of mucoperiosteum; intrasinus density that of the orbit.

2. Antrum containing fluid of low specific gravity; general dullness; duller than orbit or its fellow sinus; fluid line (sometimes); inner sinus bony wall can still be seen.

3. Pus in sinus: Marked general dullness (flat); markedly duller than orbit or its fellow sinus; inner sinus bony wall cannot still be seen.

4. Acutely inflamed: Fuzzy mucoperiosteum; fuzzy and indistinct bony outline; some opacity.

5. Chronic inflamed sinus: Hypertrophy mucoperiosteum; bony outline sharper; some opacity.

5a. In ethmoids: Sometimes can see these bony outlines sharper than usual; sometimes goes on to a break in the normal bony outline. (Law.)

6. Chronic inflamed sinus in an acute exacerbation: Hypertrophic mucoperiosteum, which appears fuzzy; bony outline quite clear; some opacity.

In the lateral view of the frontals, note the skull thickness. In this view you will note the presence or absence of the frontal sinus. In the absence of the frontals you should see cancellous bone in their place. No amount of pus or granulation tissue will obstruct them in the lateral view.

Note ethmoids especially in this lateral view. If the small cell-wall lines are fragmented, absent, or stand out with exceptional sharpness, it indicates involvement (chronic).

Sphenoid:

Lateral view: This view shows its anterior posterior size. In this view if you see a fuzziness of the anterior sphenoidal wall, this may be just a pathologic condition in the posterior ethmoids.

Verticomenal view: This view shows you best the lateral edges and lateral extensions; also shows

mucoperiosteum thickenings and general dullness or haziness at times. Granger, however, points out that this view (a) does not have positive and readily identified boundary marks; (b) that you cannot make perfect duplicates; (c) that either polyps, a marked hypertrophy of the inferior turbinate or a carcinoma may cause a normal sphenoid cell to appear cloudy.

Granger's "G" line position: This is a view of the upper border of the sphenoid, and it can show any one of the general sinus changes already noted. We find it one of the most important views. Granger states that, with this view, 95 per cent of the sphenoid sinus conditions can be diagnosed.

PROCEDURE IN EXAMINING PICTURES

1. Was the picture over- or underexposed?
2. Was the picture taken at the correct angle? Was head fixed? (Note: Mastoid bones and cancellous bone about the teeth.)
3. Anatomy: In lateral view, note skull thickness. In posterior anterior view, note relative size of sinuses.
4. General density (orbital comparison) (sometimes the reducing glass accentuates this): Fluid, pus.
5. Study mucoperiosteum. Is it fuzzy? Is there any hypertrophy? Are there polyps to be seen?
6. Study bony walls. Are they fuzzy? Is there any increased sharpness? Has there been any or a total erosion?

WHEN SHOULD WE USE ROENTGEN RAYS

They should never be used as the only method of diagnosis of sinus disease. There is a great tendency of the general practitioner, when he suspects sinus trouble, to have one flat view of the sinuses taken, in order, in his mind, to rule out all sinus disease. This should be discouraged, and the general practitioner taught that there is no easy road to the diagnosis of sinus disease.

A glance below at an outline of the study of sinus disease will show that in discarding all but x-rays, we would be bound to have a high percentage of error.

Diagnosis of Sinus Pathology:

History
Direct examination
Transillumination
X-rays
Laboratory data:
Wassermann
Smears
Fluid
Examination
Blood counts, etc.

We, therefore, must relegate x-rays to their proper place. In keeping the above outline in mind, one can see x-ray is only one phase in the diagnosis, and we must never forget that the x-ray films only show changes in the specific gravity of the tissues and sinus contents, nothing more.

However, these changes in density are often very helpful to us, and in certain conditions it seems that it would be wise for us to refer more patients for x-ray study before giving a negative report on their sinus condition. As an example: I have checked one hundred consecutive cases in an arthritis clinic in the Los Angeles County

Hospital, x-raying all of them, and it is interesting to note two things:

First: That thirty of these patients (30 per cent) showed sinus pathology in their films.

Second: That nine of these patients showing sinus pathology on their films gave *no* history of any sinus disease, which might have led me or the general practitioner to suspect sinus trouble.

As you see here, I have often been surprised to find sinus pathology where I did not suspect it from my history and examination.

Especially in the following group of cases x-rays should be taken:

1. Practically all sinus cases before operation.
2. Before making a negative diagnosis in cases being surveyed for focal infection.
3. Chronic discharging ears.
4. Postinfluenza patients not doing well.
5. Chronic bronchitis.
6. Patients suffering from colds persisting after tonsillectomy.
7. Upper toothache when teeth are negative, from dental point of view.
8. Before septum operation when patient complains of anything but occlusion.
9. Cases with high-arch palate and mouth breathers.

IN CONCLUSION

In conclusion, I advise more exact study of exposures and positions, making certain they are correct. The anatomy of the sinuses should be observed.

In general, fuzzy borders show an acute condition, sharper bony outline with thickened mucoperiosteum shows a chronic state, and general haziness indicates fluid or pus.

In osteomyelitis, or when looking for bony structural changes, one should remember that the disease is about eight to twenty-one days ahead of any visible changes to be found on the x-ray film.

Bearing in mind the relative place of x-rays in the field of diagnosis and their physical properties, one will neither expect too much nor too little of them.

143 North Brand Boulevard.

DISCUSSION

DEAN E. GODWIN, M.D. (820 Professional Building, Long Beach).—To the layman, the x-ray, because of its magic and weird properties, represents the possibility of solution of all his uncertainties and ills, and he expects an x-ray picture to give a ready-made diagnosis to any obscure condition much as he would get in a prediction of his "fortune," from a slot machine. Too often a hurried or lazy physician assumes the same attitude, and expects the roentgenologist to solve his problems and do his thinking for him.

Doctor Ghrist has properly evaluated the roentgenogram, making it but one of the several methods of arriving at a diagnosis in sinus conditions, and I note that in his "outline of the study of sinus disease," he puts the x-ray after the history, clinical examination, and transillumination. In many cases, after these are done, the diagnosis is so obvious that the roentgenogram can be omitted. In other cases, when the condition is more obscure, the picture may be the deciding factor in arriving at the diagnosis. Even when the diagnosis is complete without it, a picture is often invaluable from an anatomical standpoint before surgery of the sinuses, particularly the frontals and sphenoids.

Doctor Ghrist has given us some valuable guides in interpreting the x-ray films, and infers, of course, that the rhinologist should study and attempt to diagnose his own films. This is as it should be, for the clinician has the advantage over the laboratory man in that he can check his findings and interpretations at surgery, and thus improve his diagnostic abilities.

In my opinion, this subject should not be closed without mentioning the value in certain cases of the uses of lipiodol by the Proetz method or by injection, as this may show thickening of the mucous membranes, or polyposes that are not shown by the ordinary methods. Another point that may be spoken of is the value in certain cases of making the exposures while the patient is erect, with the x-ray horizontal to show fluid levels.

✽

HAROLD A. FLETCHER, M.D. (490 Post Street, San Francisco).—Many roentgenologists are apt to make pathologic diagnoses in reporting their findings from their x-ray examinations. These pathologic diagnoses are often found not to fit in with the clinical picture present. To a physician or a nose specialist who has not taken the time to familiarize himself with reading his own x-ray films, these reports, often accepted verbatim, start the physician and patient off on a completely false path of expensive, painful, and time-consuming treatments and operations. The roentgenologist is still much too anxious to make far too reaching positive diagnoses based solely upon his examination, instead of reporting facts of abnormal changes of density which is all he can accurately do. When he has carefully and accurately recorded his findings, it is quite reasonable for him to suggest the possibilities of the underlying pathology if he knows them.

Many general physicians, general surgeons and (unfortunately, and to their discredit) many rhinologists accept an x-ray report of, for instance, a "cloudy maxillary sinus" and, with hardly a cursory glance at either the x-ray film or the patient, advise a radical antrum operation. This is bad medicine, bad surgery, and certainly suspiciously bad rhinology.

If the various departments of medicine and surgery are going to utilize x-rays in the diagnosis of sinus diseases, they owe it to the patient and to their profession to use them intelligently. Hearing an abnormal chest sound through a stethoscope is not an indication for a rib resection, no matter how remunerative, and similarly it may be said that cloudiness and other x-ray findings in sinus pictures are not of themselves indications for sinus surgery. The abnormal findings by x-ray are sometimes of great help when fitted into their proper place with the other clinical observations. Far too much importance, however, has been attached to these findings alone.

This article is for its purpose quite complete. It points out, in the first place, what one should expect to find in a well-taken film. It points out that, unless a picture is well taken and clear, it is worse than useless to attempt diagnosis from it. It points out the various positions most useful in x-ray studies, and the various findings indicative of pathology, and it finally places the usefulness of x-ray diagnosis in sinus condition in a proper relationship. It is a paper well worthy of careful and intensive study and thought by the general practitioner, surgeon, and rhinologist.

✽

CHARLES E. FUTCH, M.D. (1930 Wilshire Boulevard, Los Angeles).—The historical and physico-chemical analysis in Doctor Ghrist's paper is of particular interest to the rhinologist, affording him a review which can only result in a better interpretation of his films.

James T. Case said: "It is too much to expect any man to be a specialist in all of the branches of medicine in which roentgenology plays a useful part." This is only too true, but it is entirely essential today that the rhinologist should have a clear understanding of x-rays of sinu-pathology, if he is to diagnose and treat these conditions.

Doctor Ghrist's suggested technique and nomenclature, if generally adopted, would go far toward righting some confusion which still exists in this field and thus assist in what is essential in all scientific work, namely, establishing a common basis of technique for universal study

and comparison. It is hoped that some such standardization will be nationally adopted.

Only emphasis can be laid upon the point already stressed by the author relative to stereoscopic films. Such films are essential to a proper interpretation, particularly in the complex ethmoid labyrinths and sphenoid cells. The remarkable anatomical variation in these cells is well known, and only by stereoscopic view can we expect to interpret pathology. The exactness of knowledge necessary to successful surgery of these regions is greatly fortified by stereoscopic study.

The author correctly states that in the diagnosis of sinus disease an entire reliance upon the x-ray would result in a high percentage of error, but there were certain instances which lack of space and time prevented him from mentioning. Particularly in children where instrumentation, and even a careful examination is difficult or impossible, x-rays are a welcome and very helpful short-cut.

As the x-ray may help, so may it deceive if certain facts are not kept in mind. Proetz and others have carried out experiments showing the extreme deception that may take place in x-rays of allergic membranes. This factor of possible error, namely, the differentiation between true hypertrophy and allergy, must be kept in mind.

Osteomyelitis of the frontal bone presents exceptional difficulty upon occasion, even in stereoscopic films. As stated my Doctor Mosher: "If there is bone necrosis, the bone is infected for an inch to an inch and one-half beyond this area, and the x-ray is not positive until necrosis occurs seven to ten days later," only emphasizing again the point brought out by the author under "osteomyelitis."

RECONSTRUCTION OF THE BREAST*

By HOWARD L. UPDEGRAFF, M.D.
Hollywood

DISCUSSION by William S. Kiskadden, M.D., Los Angeles; Gerald B. O'Connor, M.D., San Francisco; Harry M. Blackfield, M.D., San Francisco.

EVERY surgeon is faced with the necessity of giving advice regarding surgery of the hypertrophied breast. If the hypertrophy is associated with malignancy, we advise radical amputation. If it is a benign overgrowth, what have we to offer the patient?

The past twenty-five years have produced an increasing number of articles on surgery of the benign hypertrophied breast. The great majority of these have come from abroad, while the American literature has been limited to a scant half-dozen. We have copied foreign operative technique, modifying it slightly and accepting its bad as well as good points.

INDICATIONS FOR SURGICAL RECONSTRUCTION

The indications for surgical reconstruction of the nonmalignant breast are necessarily based on such factors as enlargement, difference in size, lumpiness, pain from weight, interference with occupation, and mental instability arising from inferiority complexes due to embarrassment in carrying on ordinary social activities, etc.

Breast surgery should always be authorized by a very definite reason, either physical or mental, or the end-results will not be acceptable to the patient.

* Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

ETIOLOGIC FACTORS IN BREAST HYPERTROPHY

Etiologically there is no generalization which will cover hypertrophy of the breast. One of the most generally accepted causative factors is the wearing of tight brassieres in early life, which cause atrophy of the supporting muscles and suspensory ligaments, with an impairment of the return circulation and consequent fatty deposits. There are also those instances where the body metabolism and the endocrine hook-up is such that there is a localized enlargement of the breast, either *per se* or as a part of the general overgrowth.

DETERMINATION OF BREAST SIZE

The correct size of the breast to be reconstructed is formulated somewhat upon the mental image which comes to the surgeon once the normal nipple locus has been placed. Duerer, in his book on "Human Proportions," in 1528 presented a series of sketches of female figures and their measurements which have been a standard for artists ever since. Granted that the nipple normally is over the fourth inner space, Duerer locates it by dropping lines from the acromioclavicular joint to the umbilicus and places the nipple where this line crosses the fourth inner space. Today the age and wishes of the patient are also important factors.

There has been, as with a number of other newer surgical procedures, a great deal of controversy as to the merits of mastopexy, or breast-shift. The greatest objection to the simple breast-shift has been the possible loss of function, which is not to be dismissed lightly. However, the fact that 80 per cent at least of our hospital postpartum patients are non-nursing mothers, is enlightening. It must be noted in passing that none of the operations described in the literature are dedicated to restoring function. Neither is the average patient seeking breast reconstruction particularly interested in preserving function in an already semi-atrophic breast.

MALIGNANCY AND NON-MALIGNANCY

The question of a differential diagnosis between malignancy and non-malignancy of the breast is one which has been thoroughly discussed in the literature. In passing, however, a recent article by Rodman states that if a patient under thirty-five has a lump in the breast which does not change for two months, he recommends local excision for microscopic study. If over thirty-five and the same situation, amputation is advised; because one-fifth to one-fourth of women over thirty-five, and especially over forty-five, develop carcinoma following chronic cystic mastitis.

Lumps in the breast, however, are mechanical obstructions to breast reconstruction and must be recognized as potentially influencing the character of operation best suited to the patient's condition.

THREE TYPES OF NON-MALIGNANT BREAST

From the surgeon's standpoint there are three types of non-malignant breast in considering reconstruction:

1. The moderately enlarged breast free from lumps that a simple mastopexy, without a lower

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 1.—Hypertrophic nonfunctional breasts. The patient complains of pain and discomfort from weight. Breasts are lumpy and skin is excoriated underneath. Has been advised amputation. Seeks reconstruction if possible.

Fig. 2.—A full thickness graft, including the nipple and surrounding areolar tissue, is transplanted to a point where the normal nipple line crosses the fourth or fifth inner space. The area is prepared by removal of an oval piece of skin slightly smaller than the graft. The graft is anchored in place by a piece of dental wax or stent cut to size. This is held in place by sutures to the surrounding skin for six to eight days.

Fig. 3.—The complete breast content has been amputated and the flap fashioned to form a small nonfunctioning breast. This procedure is recommended only in surgery of the very large lumpy breast where the usual mastopexy or breast shift would be dangerous.

keyhole incision in the skin flap or excision of the gland tissue, will rebuild.

2. The definitely enlarged breast needing a mastopexy, utilizing the keyhole incision and removing varying amounts of breast fat and tissue including an occasional lump.

There are many different types of operation for these first two classes of breasts. Each one was very likely devised to fit the type of breast involved, and has to do with the reconstruction of the breast with the nipples left attached. The main differences are in the plan of incision and the procedures to maintain a functional breast. A general surgeon with an accurate knowledge of the blood and nerve supply of the breast, plus an understanding of the planning and handling of skin flaps and grafts with some preoperative meditation and power to visualize final results should be able to perform any of them.

However, the cases must be carefully chosen, as a body metabolism which is markedly off will complicate matters exceedingly. After one has had to care for the various complications following operative work of this type, he becomes very discerning in his acceptance of new cases.

3. The third type is the large nodular hypertrophic breast, which presents marked obstacles in following the surgical plans for reconstruction as applied in the previously mentioned types. These are the breasts usually amputated by the general surgeon. Included in this class is the large breast, which is amputated like the appendix because at times it shows symptoms which do not altogether clear up. For example, the painful lump in the breast occurring each period; also the polycystic fibromas and the breast of chronic cystic mastitis. Added to these are various conditions of the breast, so that when the patient asks of the doctor, "Do you think I should have my breast removed to avoid possible danger in the future?" the doctor is forced to answer, "Yes."

NON-FUNCTIONAL BREAST HERE DISCUSSED

It is the surgery of this type of non-functional breast that I wish particularly to discuss in this paper. A well-planned amputation, carefully performed with a preliminary full thickness nipple graft (Fig. 2), will allow removal of all lumps and the salvaging of sufficient skin and fat to form an acceptable, normal-looking breast.

A

B

Fig. 7

Fig. 5.—Young mother who was unable to nurse her baby desires relief from painful heavy breasts, but hesitates to accept radical amputation deformity. Breasts are lumpy and painful, and not good risks for the usual reconstructive technique.

Fig. 6.—Twenty-one days after first stage, with nipple grafts complete take. If portion of graft does not take, additional repair may be made from areolar skin remaining on original site.

Fig. 7.—Eight weeks following first stage. The patient does not wear brassieres and is free from discomfort and pain. These are nonfunctional breasts, but have ordinary skin sensation in both skin and nipple.

Transplantation of the nipple was first reported by Max Thorek in 1922. He did it as an experiment, and was surprised to find that he had a partial take of the graft. Later he reported that, histologically, there was evidence of the nipple surviving. His method at present consists of doing one breast at a time. He reduces the breast to the size he desires, then sutures the nipple where he thinks it should be and dresses it with dry gauze. A week or ten days later he does the other breast. Up to now I have not been able to find any other paper on the subject of free graft of the nipple in American literature.

I can see no objection to this method except that, in placing one nipple at a time, the second breast will differ from the one already done and in the process of healing. Again, when a nipple is transplanted to a flap which has just been raised, one is taking a chance of losing the graft from insufficient blood supply and an inability to apply satisfactory pressure.

OPERATIVE PROCEDURE

My method has been to transplant both nipples at the first stage. This can be done either under local or general anesthesia. The defects left by removal of the nipples are repaired by undercutting, and bringing the circular incisions in the areola together in a straight line. The nipple and areolar skin to be transplanted is denuded of its subcutaneous layer and planted in its new bed over the fourth inner space, from which an oval area of full thickness skin has been removed. The grafts are sutured to the margins and dressed with vaseline gauze, over which a piece of modeled stent is laid. This is held in place by heavy-silk sutures through the graft and skin margins and tied over the stent for seven to ten days. Many patients facing breast amputations are not particularly interested in the preservation of the nipples, provided they can be assured of a semblance of a breast. For these the second stage may be substituted for the first.

The second stage may be performed any time after fifteen to thirty days, as the nipple grafts will have taken by that time. The incision line is marked with the patient standing and the flap made somewhat larger than in an ordinary breast-shift (Fig. 4 c). It is also made as thick as possible, and includes little or none of the breast tissue. This not only grants additional immunity to impaired circulation, but the contraction of the thick flap offers extra material for molding the new breasts (Fig. 4 d). If there is not sufficient material left after amputation of the breast, fat may be taken from the undersurface of the amputated breast and skin, and used as a free-fat graft with surprisingly little absorption.

The breasts are dressed with vaselin gauze and marine-sea sponges, cut so as to aid in forming the breasts and held in place with stockingette bandages. Seven to nine days are sufficient for hospitalization, and ordinary duties may be resumed in two to three weeks. Freedom from brassieres may then be granted and the patient assured of the cessation of her breast worries. There is a tendency for the breast fat to increase somewhat later, giving a more pleasing contour.

The complications of the ordinary breast-shift, namely, hematoma, skin slough, nipple loss, etc., which are more likely to occur in efforts at reconstruction of the third type of hypertrophied breast, are thus avoided. Surrounding skin enervation will give sensation to the nipple in two to four months. Peculiarly enough, the menstrual difficulties usually associated with the hypertrophied breast are greatly relieved.

IN CONCLUSION

In conclusion, I wish to call attention to the thought that if we can offer an acceptable, non-functional cosmetic breast to our patients, who are procrastinating against breast surgery through fear of deformity until too late, then we are contributing another helping hand in the fight on cancer.

6777 Hollywood Boulevard.

DISCUSSION

WILLIAM S. KISKADDEN, M. D. (803 Wilshire Medical Building, Los Angeles).—As brought out by the essayist, the enlarged pendulous breast can be reconstructed both functionally and cosmetically by a variety of procedures. The greatly enlarged pendulous and nodular breast, however, because of its very size responds less well to the usual operative process. This method of transplanting the nipples will give a cosmetic result quite superior to partial amputation. Whether the loss, or at least diminution of nerve supply, the danger of nipple necrosis, the definite division into two operative procedures, when transplanting the nipple, is wiser than perhaps a fair cosmetic result from one of the other methods of treatment, is a question to be answered by the individual surgeon. Certainly, when amputation of the entire glandular breast tissue is considered, this procedure will give a much better cosmetic result. The author deserves credit in helping to pioneer an operation which, on first thought, would seem to be fraught with considerable uncertainty. It is a procedure which has a limited but definite place in the reconstructive surgery of the breast.

✽

GERALD B. O'CONNOR, M. D. (490 Post Street, San Francisco).—Reconstruction of the idiopathic, hypertrophied breast has become an accepted rational surgical procedure to bring relief to those persons so afflicted, whether from a symptomatic or mental point of view. This work has been brought about over a period of years by enlightening contributions, both foreign and American, of men interested in the physiologic reconstruction of enlarged mammary glands. In the enlarged functioning breasts, proper surgical reconstruction will not interfere with breast function in the majority of cases.

Doctor Updegraff's method, of the primary free transplantation of the nipples, is a contribution to the type of breast surgery as reported by Max Thorek in 1922. His points of delayed healing and, more likely of nipple necrosis when following the Thorek technique, are well taken, and his sequence of nipple transplantation certainly diminishes these possibilities. The proper location of the new nipple is a difficult task, in spite of preoperative planning, and a full allowance should be made for the redisturbance of chest skin following undermining and elevation for the newly constructed breast.

I wish to emphasize the fact that the free transplantation of the nipple is a Wolfe graft, and that this type of graft, even in the most experienced hands and under ideal conditions, is very uncertain as to complete take, so that any surgeon contemplating Wolfe grafts of the nipple should warn the patient as to the possibility of partial or complete loss of one or both nipples. Free transplantation of the nipples should rarely be done, and I am in accord with the views of the author that it should be reserved for those large, nonmalignant nodular breasts for which amputation has been advised.

✽

HARRY M. BLACKFIELD, M. D. (350 Post Street, San Francisco).—The author has briefly but excellently reviewed our present ideas on the subject of breast hypertrophy. His paper again emphasizes the fact that reconstruction surgeons must be well-grounded in the field of general surgery, as well as in plastic surgery.

The recommendation, that one should think of breast reconstruction when considering amputation of the breast for a nonmalignant condition, is to be commended. This holds true particularly for young women. Inasmuch as two operative procedures are required for breast reconstruction, as against one when simple amputation is done, the patient should be allowed to make her choice.

A word of warning, however, should be given about the use of free full thickness or Wolfe grafts. Even men who have had a great deal of experience and success with this type of graft occasionally have failures, and the novice will find that his percentage of successful takes will be very low.

THE FEET IN YOUNG CHILDHOOD: SOME FACTS AND FALLACIES*

By EDWIN F. PATTON, M.D.

Los Angeles

DISCUSSION by Clifford Sweet, M. D., Oakland; Maynard Harding, M. D., San Diego; E. Earl Moody, M. D., Los Angeles.

SEVERAL conditions of childhood, including rachitic deformities, faulty posture, Frölich's knock-knee, epiphyseal disorders and minor foot defects, fall into the fields of both pediatrics and orthopedics, yet belong strictly to neither.

Since most orthopedic men are primarily mechanical-minded, and are not fully appreciative of such pediatric considerations as constitutional type, nutritional state, and physiologic efficiency; and since most pediatricians involuntarily shudder at the thought of mechanical appliances, these conditions have come to occupy the position of medical stepchildren, and consequently are bound to suffer some neglect when managed by one or the other specialty alone.

Minor foot defects probably suffer most, since reciprocal reference of such cases is hardly felt worth the cost. Yet, because of this, their management has become slipshod, both orthopedic men and pediatricians having rather unthinkingly allowed themselves to pick up and adopt certain fallacious conceptions regarding them.

NO EMPIRIC STANDARD OF FOOT CONFORMATION AND DEVELOPMENT

Fallacy number one is that there is such a thing as an ideal standard of foot conformation and development by which all feet should be judged. This is just as untrue as that the standard weight-height-age tables apply unequivocally to all individuals. Actually, there is as much variation in normal feet as there is in normal noses. Frequent repetition has factualized in most of our minds such statements as these: that longitudinal arches should be established when walking commences, and that the transverse arch should develop soon after walking begins; that the normal foot has a straight inner border, an appreciable arch and a straight heel-cord when the weight is put upon it; that there should be a vacant space in the foot-print under the three inner metatarsal shafts, scaphoid, and the forepart of the calcaneus; that if all these criteria are not met the foot is not normal. I cannot subscribe to these statements since, in fifteen years of observation in pediatric and orthopedic clinics and school systems, I have seen feet exhibiting wide variations from these standards which, from the standpoint of function, were all that could reasonably be desired.

Feet are part of the body as a whole, partaking of the characteristics of the rest of the body make-up. They vary with hereditary or constitutional body type, embryonic defects, developmental factors, vagaries of physiology, nutritional situations, general tissue tone, general and local state of

* Read before the Pediatric Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

health or disease. They must be judged in relation to all of these considerations, plus, most important of all, how well they serve their owner. Conformation is not the whole answer by a great deal. In many instances feet which are functionally highly efficient would not satisfy artistic criteria of form. In many other instances well-formed feet are unduly fatiguable, awkward, or painful on use.

In pediatrics there is frequently encountered a type of child which I think is best described as hyperelastic, in whom the weight-carrying structures are of perfect strength and tone, but stretch out more under stress than the average. These youngsters are endowed with hyperextensible joints; even after walking begins, it may be possible to bring the dorsa of their feet almost up against their shins. When their feet are allowed to dangle they rest in perfect position, but when the child steps on them, naturally they pronate and the forefoot goes into eversion.

Carpal development and blood chemistry are normal. General health and development are perfect. How can this then be considered an abnormal condition requiring cumbersome appliances for correction? In my opinion these children should be given the test of time, and in almost all instances after a few months or years nature will diminish the excess elasticity to the point where arches will remain perfect when body weight is applied. Of course, if awkwardness, fatiguability, or pain on use develops in this kind of case, that is a signal for support. My answer to the contour fallacy, then, is that while efficiency and generally accepted standards of contour usually do go together, they are not invariably parallel; and the answer to the time-of-arch development fallacy is that it varies within extremely wide limits and that it is not nearly so important, anyway, as is the relationship between development of functional capacity consistent with the increasing burden as growth in size and weight takes place.

STIFF SHOES ARE NOT NECESSARY

Fallacy number two is that babies need stiff shoes to help them learn to walk. The truth of this is that babies learn to walk at a time and at a rate determined by their neuromuscular development, and shoes have very little to do with it. For the perfectly normal foot, shoes are not necessary at all, and if worn should be regarded as merely gloves for the feet, to protect against cold and injury. If walking is delayed by abnormally weak feet, it will take more than the mere ankle-stiffening provided by shoes to enable the child to catch up.

CORRECTION OF PRONATED FEET

Fallacy number three is that all pronated feet need to be corrected. In the light of instances already given, I feel that this must be qualified to read: If pronation is accompanied by awkwardness, undue fatiguability or pain on use to such an extent that potential efficiency is cut down, then artificial aid is indicated. Otherwise, time is the only appliance that is reasonable to use.

RELAXED ARCHES

Fallacy number four is that all relaxed arches require correction. The answer is identical to that given for pronation, namely, the imperative rests on the disabling accompaniments of relaxation—not on the relaxation itself.

SHOE-HEEL FALLACY

Fallacy number five is that pronation can be corrected by tilting up the inner border of the shoe-heels. This may suffice for a few days in new shoes, but after this short time the leather gives and the heel rotates around into its former bad position. Without accompanying support under the scaphoid bone to hold up the arch which always goes down when the foot pronates, tilts are about as good as useless.

CORRECTION OF FLAT FEET

Fallacy number six is that flat-foot can be corrected by wearing commercial orthopedic shoes. There is no orthopedic shoe on the market which carries full arch correction. The features usually present in these shoes are: straight inner border, roomy toe, steel shank, advanced inner counter, advanced elevated inner border of heels, all on a basis of extrasubstantial construction. The final result is about half of the amount of arch correction that is needed. Too many pediatricians, and even orthopedic men, consider it enough to send their patients with pronation or arch depression to some shoe clerk with whom they are particularly friendly, carrying an order to fit suitable shoes. This is a halfway measure analogous to sending a child with a severe refractive defect to an optometrist. If a foot really needs an arch support, nothing short of a made-to-measure semi-rigid arch plate fitted inside of shoes which will hold the foot in place on the plate will suffice. The best arch supports for all ages are those of metal, the size and weight being regulated to the individual. No other material has the permanence, the physiologically favorable amount of springiness and the adaptability of metal.

ARCH PLATES

Fallacy number seven is that all cases of flat-foot will be corrected by arch plates and suitable shoes. Flat feet secondary to malnutrition, anemia, chronic devitalizing disease or devitalization by acute disease, will not respond until the basic cause is corrected, and general good health restored. Acute foot collapse of puberty will not be overcome by mechanical means until endocrine readjustment has taken place either spontaneously or with medical assistance. There are certain congenital flat feet which nothing short of operation will influence.

FOOT EXERCISES

Fallacy number eight is that flat-foot can be corrected by exercises. Muscle-pull is a very minor element in arch maintenance. Exercising the inverters of the foot ten or *fifteen minutes* a day can have but little, if any, influence on what they will do during the *twelve* or so weight-bearing

hours of the day. Besides, if these muscles are atonic, it is usually because the entire muscular system is atonic as a result of one of the conditions just mentioned. The logical approach, then, is by way of improvement of general condition. While the customary exercises can do no harm, probably much more would be gained by rest and medical care. A few years ago, in an extensive survey of Los Angeles school children whose flat feet and bad posture did not respond to corrective physical education, I very quickly found the reason. Practically all of these children were malnourished, subvital and chronically fatigued. The money spent maintaining an expensive school department could have been applied to much better purpose in giving these children good food, adequate vitamins, rest, sunshine, and fresh air. Under such a regimen their arches and backs could not have shown less improvement, and I confidently believe would have shown a great deal more.

EARLY WALKING

Fallacy number nine is that flat-foot is caused by too early walking. Walking seldom begins till bones, ligaments, and muscles are ready; nature sees to that by not providing the impulse before. If structures are not of proper tone, precocious walking practically never takes place. When walking does start, if structures are normal, they will hold up. If they are not adequate they will go down no matter to what age weight bearing is delayed. The fault is with the structures and not with their use, and restricting walking will make no difference unless structural condition is naturally or artificially improved in the meantime.

SHOE WEDGES

Fallacy number ten is that a wedge under the inner edge of the foot will correct bow-leg or knock-knee. If a bow-legged or knock-kneed child has, in addition, feet which need support, supports should be provided for the sake of the feet themselves and not to influence the legs. It is inconsistent to ask Wolfe's law of "growth in the direction of weight-bearing line" to work the miracle of correcting opposite deviations by identical adjustments. Bones grow crooked or straight because of the internal factors of calcium phosphorus metabolism and neurotrophic guidance, unless a strong external influence is applied; and this influence must be far more powerful than a simple shoe tilt. If knock-knees or bow-legs do not improve, or grow worse, under medical treatment, then nothing short of braces will get the desired results. It must be remembered that most infant legs are normally bowed, and most run-about legs go through a normal knock-knee phase. Both of these correct themselves unless there is some definite underlying defect present.

HIGH HEELS

Fallacy number eleven is that high heels should never be worn. Young girls who have been troubled for years with minor arch depression frequently become trouble-free when they reach the high-heel age. High-heeled shoes have per-

force a high built-in arch, higher in fact than most arch supports; and unless the foot is too badly relaxed they often give that little added support which is all the foot needs to assume good position and function. Of course, sharp, narrow toes, such as many high-heeled shoes have, are vicious, but the heels themselves need not be absolutely condemned.

SUMMARY: MINOR FOOT DEFECTS

To sum up minor foot defects, then, we find that the primary essential in appraisal is to apply a criterion of reasonable functional efficiency in relationship to the child as a whole; and the primary essential of treatment is to bring general condition to par. The secondary essential of treatment follows, namely, *complete* and not *halfway* measures of mechanical positioning. A practical working foot, not a visionary ideal, should be our goal.

MAJOR FOOT DEFECTS

Of the major foot defects, the one that concerns the pediatrician most, is perhaps Köhler's scaphoiditis, which is now considered to be a partial death of the scaphoid bone from ischemia, usually precipitated by trauma, but occurring on a basis of poor calcium-phosphorus metabolism. It is as essential for the child with this disease to have nutritional guidance and possibly endocrine work as to have orthopedic care.

Next in pediatric interest would come perhaps the chronic sprain of the calcaneal apophysis frequently seen just prior to puberty, to which the last statement is equally applicable.

When feet are encountered which have bony knobs or prominences, especially at the scaphoid, the rule is that if they give sufficient mechanical trouble by rubbing and bursa formation, the prominences have to be removed surgically.

There is a problem foot known as the metatarsus primus varus foot in which the first metatarsal is set with its base more laterally and its head fanning out more medially than usual, with pronation as an almost invariable accompaniment. The bad part about this foot is that the great toe is thrown medially where it encounters shoe pressure which predisposes to hallux valgus. Pronation of the foot decreases the fanning of the first metatarsal and thus lessens the tendency to hallux valgus. Overcoming the pronation increases both of these. The question here is of major orthopedic importance involving a decision as to which is worse, pronation or hallux valgus. The only way around it is by open osteotomy in the proximal third of the metatarsal with suitable realignment of the distal portion.

As regards other major defects it is essential for the pediatrician to be able to recognize them, to know that the earlier treatment is instituted the better the results, and to know also that treatment must continue until growth is complete because the influences which cause such conditions in the first place persist indefinitely. This last statement is particularly true of club-foot, and because of tendency to relapse after correction I have devised a celluloid maintenance slipper which can

be worn inside of an ordinary shoe. When the weight is put down in this device the foot is forced into slight overcorrection. Celluloid does not give way, a characteristic which overcomes the drawback of leather which after a short period warps with the warmth, moisture, and pressure of the foot and allows the deformity to recur.

Congenital claw-foot is probably, like club-foot, a result of neuromuscular deficiency allowing heel and forefoot to drop down and the plantar ligament to shorten. Because of the short lever arms involved, surgery such as plantar fasciotomy and tarsal stabilization is often necessary.

A well-developed hallux valgus usually requires surgical reconstruction of the first metatarsophalangeal joint even in childhood.

The foot of cerebral palsy is a complicated problem, the objectives being: by surgery or braces to bring the foot into a neutral walking position and to hold it as steady as possible in this position. Tendon lengthenings and stabilizations are frequently necessary.

In poliomyelitis each foot is an individual proposition in which the material at hand is appraised and is rearranged to bring about maximum functional adequacy. Lateral stabilization is the most frequently helpful measure. Tendons may be transplanted, but too much reliance should not be placed on this measure since the power and the performance of transplanted muscles are unpredictable, and what may result after a period of years may turn out to be a new defect in itself.

IN CONCLUSION

To conclude, then: for defective young feet to receive optimal care it will be necessary for orthopedic men and pediatricians to train themselves in each other's specialties or else to cooperate more than they do at present.

3875 Wilshire Boulevard.

DISCUSSION

CLIFFORD SWEET, M. D. (242 Moss Avenue, Oakland). Doctor Patton has presented a matter that has a very important place in child welfare.

I cannot agree, however, that "most orthopedic men are mechanically minded." On the contrary, I have found among them a very real appreciation of "constitutional type, nutritional state, and physiologic efficiency." They probably differ from pediatricians, more generally, in point of view because by far the greater number of their patients come to them, either because they have the more extreme mechanical faults or because physiologic efficiency has fallen to the stage of painful symptoms, and they may, therefore, demand mechanical or surgical treatment. The pediatrician more generally sees the patients with minor defects, or with the more serious defects, while preventive measures may still be effective. Also while the orthopedist has generally more special knowledge concerning body mechanics, the pediatricist has the great advantage of studying many children while they pass their successive stages of development.

I agree entirely that feet should not be judged solely on their form and, especially, that too much attention should not be paid to the height of the longitudinal arch. I am reminded of the West Virginia recruit, a barefooted and, therefore, flat-footed mountaineer, who, having been rejected for military duty because of flat feet, remarked: "Well, I'll have to walk that five hundred miles back home again."

I commend to all who care for children Doctor Patton's thought, "Feet are part of the body as a whole," and that

rest and improvement of the child's general health are fundamental if any other measures are to be carried to a satisfactory degree of success. He has not mentioned, however, that the feet are not only a part of the physical make-up of the individual, but are also only one group of the mutually interacting muscles, tendons and joints which enter into and determine the efficiency of the patient's entire system of body mechanics. For example, unbalanced feet (pronated and everted) are only one part of a Class C posture with its forward thrust head and shoulder girdle, weak abdominal muscles, lumbar lordosis, anterior rotation of the pelvis, internal rotation of the thighs, external rotation of the legs and either marked shortness of the posterior calf muscles and tendons, with a resultant pull that forces and holds the foot in eversion and pronation, or abnormally long posterior calf muscles (the hyperelastic child), which do not support the foot sufficiently to prevent marked pronation. While it is true that correction of the feet has, no doubt, some favorable effect upon the entire mechanics of the body, the part played by this correction alone must remain a small one. The faulty mechanics of the entire body is the cause, and the malposition of the feet only one of many effects. A child may have perfectly corrected feet and maintain a Class C posture, but correction of the posture to Class A, or even B, is impossible without simultaneous, marked improvement in both the weight-bearing position of the feet and their function in locomotion.

Stiff shoes are not necessary, and actually impede the child's progress, from the infantile stance in which stability, while standing, is the only objective, and forward movement is accomplished by shifting the weight alternately from one foot to the other, while the center of gravity is moved forward in a plane parallel to the ground; to the more advantageous method which comes with better coordination, enabling the child to reach forward with the foot to grip a new point of leverage and propel the center of gravity forward much more rapidly and effectively in a succession of connecting upright arcs. Reasonably stiff-soled shoes, with a heel one-half inch or more in height attached, are very useful in assisting the child who walks late and badly because he has abnormally long posterior calf muscles. This simple appliance will allow the abnormally long muscles to shorten and will spare the feet, usually congenitally weak, from the undesirable changes that follow prolonged use in the weak, pronated position.

All babies are bow-legged, and the legs straighten with walking. All children become knock-kneed and have pronated feet, reaching the height of this stage in normal development at three years of age. At the age of five, six and, at the latest, seven years of age, the knock-knee will have disappeared and pronation will have largely righted itself. We may be doing harm (at least making parents unnecessary expense) and we are certainly doing no lasting good when we interfere, except in pathologic states, with any condition which is a part of the normal growth and development of children.

✽

MAYNARD HARDING, M.D. (700 Electric Building, San Diego).—Discussion of Doctor Patton's paper within the limits of space available is not possible. Speaking from the standpoint of an orthopedic surgeon, I would say that the essayist has set up a row of straw men to knock over for the purpose of emphasizing his very common-sense conclusions. Certainly, his so-called fallacies are not believed by my confrères, to my knowledge.

The important thing stressed by his conclusion is cooperation of the pediatricist and orthopedist for mutual benefit and broadening.

✽

E. EARL MOODY, M. D. (3780 Wilshire Boulevard, Los Angeles).—Because Doctor Patton has listed as "fallacies" so many of our simple procedures for the correction of minor difficulties of the feet of children, he has left us with few "facts." I agree with him, however, when he states that there is no ideal standard of foot conformation. This viewpoint will save us from a dilemma, similar to that which overwhelmed us in the old days, when we rigidly adhered to the height-weight tables to measure nutrition in children.

I would emphasize his observation that the general nutritional picture of the child has much to do with efficiency in function of the feet. General strength and good vitality usually make certain such qualities in the feet. I am glad to see him emphasize the fact that shoes are worn as gloves for the normal feet. The most flexible shoe possible is ideal for the normal foot of the rapidly developing child.

Do not, however, some of Doctor Patton's ideas smack somewhat of nihilism? If heel-lifts, orthopedic shoes, and exercises do little or no good, then it seems that we are left with very little to do for these minor difficulties, except to correct the general nutrition of the child. I believe we would be amiss if these simple, and at least harmless, procedures were omitted in indicated cases. Perhaps the child would grow out of such minor difficulties as pronated and flat feet and knock-knees if we did nothing. However, if we failed to use these corrections, the blame would be ours should the child not make these adjustments. I have seen too many children rapidly and permanently improve when these simple, indicated corrections were made, to be willing to call them fallacies. I believe them to be too valuable as aids in the problem of nutrition and development to discard them.

✱

DOCTOR PATTON (Closing).—Doctor Sweet's discussion adds significant things which time would not allow in the original.

Doctor Harding—and San Diego—are to be congratulated if their community does not face, as does Los Angeles particularly, the widespread influence of confrères and lay bodies whose ideas are in accord with the fallacies which he so euphemistically terms "straw men."

Doctor Moody is not disagreeing, because there cannot be any possible objection to utilization of the simple measures he mentions; especially if—as I am sure is automatic in Doctor Moody's practice—the proper medical care is given at the same time.

PERIPHERAL ARTERIES: THEIR IMPORTANCE IN INDUSTRIAL PRACTICE *

By FELIX PEARL, M.D.
San Francisco

DISCUSSION by *Vernon P. Thompson, M.D., Los Angeles; Emile Holman, M.D., San Francisco; William J. Kerr, M.D., San Francisco.*

DURING the past few years the attention of the profession has been focussed, more than ever before, on the necessity for a clearer conception of the nature and course of affections of the peripheral arteries. The resultant investigations have borne fruit, so that at the present time the diagnosis and treatment of these affections rests upon a firmer and more accurate basis than was ever dreamed of previously.

There is no doubt that many insurance companies are being heavily taxed by the financial burden of patients who are suffering from manifest or occult chronic arterial disease, and that many of these patients are losing the benefit which early diagnosis and rational treatment offer them, not only for the present, but for the future as well.

In discussing the rôle of the peripheral arteries as related to industrial practice, one may divide the subject into two broad phases: (1) Direct injuries to previously normal peripheral arteries, and (2) industrial accidents occurring in individuals who have chronic arterial disease.

INDICATIONS AND TREATMENT

Contusions and lacerations of large arteries are the most common direct injuries. If the main artery to an extremity is completely severed, the vessel should be immediately sutured if it is possible to approximate the ends. If it is cut two-thirds through, it should be converted into a complete section. The Carrell technique is used in our department of sympathetic and vascular surgery. Only three weeks ago, the writer successfully performed circular arteriorrhaphy of a severed brachial artery in a child of nine years. If suture is impracticable, it may be necessary to transplant a section of vein or to ligate the artery. For arterial ligation silk or tape is recommended, which is about one-fourth the diameter of the vessel to be ligated. According to the "Golden Rule" of Matas, the artery should be ligated directly at the bleeding point rather than in continuity at a distance from the injured site. I follow the practice of anchoring the main ligature by a mattress suture of fine silk, which passes through all the coats of both walls of the artery and embraces the ligature. This prevents the ligature from blowing off. Whenever the main artery to a normal extremity must be ligated, the question arises as to the desirability of ligating the main vein at a higher level. This should be determined in the individual case at the time of operation, utilizing the response to the Henle-Coenen and the Von Frisch tests for the competency of the collateral circulation, rather than by any set rule to ligate or not to ligate in every instance. To secure permanent ligation the vessel should always be transected between ligatures, and the cut end separated. When the artery is cut, one obtains the same effect as by periarterial sympathectomy in temporarily eliminating vascular spasm, which is often a factor of tremendous importance in the clinical picture of ischemia. The use of suction pressure therapy in cases which show evidence of dangerous vascular insufficiency may also be considered. Acute traumatic thrombosis of the main artery is a difficult problem. Here, opening the artery and attempting to remove the thrombus are at times indicated if tissue death is apt to ensue. At operation periarterial sympathectomy should be performed above the site of thrombosis to eliminate vascular spasm for a period of several weeks, during which time a competent circulation may have developed. At the same time, if it is considered wise, the main vein may be divided proximal to the site of arterial injury.

Large arteries may be eroded by processes secondary to trauma, which attack the wall from without, such as abscesses, cellulitis, and thrombophlebitis. Recently, a patient was referred who had had an extensive traumatic thrombophlebitis of the inner aspect of the right thigh, complicated by multiple pulmonary infarcts and followed by a sudden hemorrhage from an eroded femoral artery. The surgeon in charge acted promptly, and ligated in continuity the femoral artery above the site of erosion. At the present time, fifteen months after ligation, the dorsalis pedis pulsation is just felt, the extremity is warm and well nourished,

* From the Clinic of Sympathetic and Vascular Surgery, Mount Zion Hospital.

Read before the Industrial Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

and vasomotor studies show a normal vasodilatation level. He has symptoms due to spasm of the arteries of this extremity brought on by exercise, which prevents him from working. These symptoms are not produced during the time that the homolateral lumbar sympathetic chain is blocked with novocain. I have advised lumbar ganglionectomy to relieve this disabling arteriospasm. Abnormal arteriovenous communications may occur from puncture wounds which injure simultaneously the vein and adjacent artery. These interfere with the competency of circulation of the extremity and throw a severe load on the heart. The collateral circulation which results from arteriovenous aneurysm is tremendous, and there is little danger in attacking these surgically if one waits from four to six months. The ideal treatment is ligation of all the vessels, arterial and venous, which open into the sac, and removal of the aneurysm under scrupulous asepsis. This differs from the treatment of traumatic aneurysms in which the sac should be preserved to keep valuable collateral vessels intact.

We now come to the consideration of the patient with chronic arterial disease. The usual type of history and the methods of study are exemplified by the following case reports.

REPORT OF CASES

CASE 1.—A man of forty-four years was referred by one of the major insurance companies for special examination, to determine whether arterial disease was a factor in a long-continued disability. He had no symptoms until August 23, 1933, when, while employed as a tractor operator, the ends of the fingers of the right hand were struck by the steering lever. Many of the details of the history were elicited only after careful questioning at the time of special examination. A few days later, small gangrenous spots appeared on the tips of the index and ring fingers, and finally sloughed in about three weeks. The right middle finger became bluish, swollen and exquisitely tender, so that on September 9, 1933, he was forced to discontinue his employment. On September 20, 1933, "pus" accumulated under the nail and the nail was removed. The entire nail bed then became gangrenous, separating about a month later. X-rays showed a fracture of the terminal phalanx. Healing was so delayed that the terminal phalanx was amputated, and after the stitches were removed the wound edges separated and became infected. On March 8, 1934, the wound was healed, but opened again soon afterward, extruding sequestra and forming small abscesses followed by sinuses. This never again healed, and on August 21, 1934, amputation was done at the proximal interphalangeal joint.

About March 14, 1934, he was attempting to turn a valve when he felt a sharp pain in the index and middle fingers of the left hand. There was no direct injury. In the latter part of April, gangrenous spots appeared on the tips of these fingers, the slough separated, leaving discharging ulcers which did not heal until June 27, 1934. A few weeks later pus accumulated under the nail of the left index finger and the nail was removed. The nail bed became gangrenous, and sloughed in about two weeks, exposing the bone. The bone is still exposed. His left index and middle fingers became cold and cyanotic in cold weather.

On examination it was found that the right radial and brachial pulses were diminished. Both hands blanched on elevation and became ruboric on dependency. The hands were exposed for thirty minutes to a constant room temperature of 16.7 degrees centigrade. The right hand was very cold to the wrist by actual measurement with the dermaterm. There was a diffuse blotchy cyanosis involving the entire hand, worse on the right index finger, which was almost purple. The picture suggested vasospasm. The

scars of the previous ulcers were visible. The sutures were still in place from the recent amputation at the proximal interphalangeal joint of the middle finger. The left hand also showed a blotchy cyanosis of the entire hand; especially marked on the index and middle fingers. The hand was cold, but about 2 degrees centigrade warmer than the right. On the tip of the left index finger was an ulcer of its dorsal surface, exposing about one centimeter of the bone of the terminal phalanx. The bone was dark and necrotic. The picture was typical of arterial disease.

The next point in the investigation was to determine whether the evident arterial disease was due to spasm or occlusion. Both hands were exposed to a room temperature of 15.6 degrees centigrade for thirty minutes, and the surface temperatures measured. The left inferior cervical, first and second thoracic sympathetic ganglia were then suffused with novocain by the posterior route. Although complete sympathetic ablation was shown by a typical Horner's syndrome and anhidrosis of the left upper extremity, there was no rise in surface temperature of the digits or change in color. A similar procedure was carried out on the right without effect. This indicated occlusion without spasm. The clinical picture, however, was so suggestive of spasm that it was thought best to check the results. The right ulnar nerve was blocked at the elbow. There was anesthesia in the ulnar distribution, but very little rise in surface temperature of the little finger, although the hypothenar eminence reached almost the normal vasodilatation level. These studies showed that the arterial disease was occlusive in nature and had only a slight element of spasm.

The feet showed absent dorsalis pedis pulsations with blotchy cyanosis similar to that seen in the hands. On the basis of the history and special studies, the diagnosis was made of chronic obliterating arterial disease of all four extremities, worse in the upper extremities; probably thromboangiitis obliterans. The underlying pathology was, of course, not compensable.

COMMENT

It is surprising that with such a typical history and objective findings during an entire year of treatment by good industrial surgeons, arterial disease was not suspected until his last amputation. The realization that severe chronic occlusive arterial disease has been the dominant underlying factor in his disability, and that the outlook is for progression of the disease, is of great significance in the further handling of this case.

CASE 2.—Another male, age thirty years, was employed in making and bottling preserves. He claimed that his feet and hands were wet almost constantly from the drainage which, he stated, contained acid used in the preservation of the fruit. In about May, 1935, a crack appeared in the tissues of the right heel, which became painful and ulcerated. About four weeks later the right second toe became painful, and within three weeks of the time had become gangrenous. He was treated with suction pressure therapy from July 17, 1935, until August 7, 1935. On September 19, 1935, this toe was amputated. In spite of the continuation of suction pressure therapy, marked swelling appeared on all the toes of the right foot, extending to the ankle, and gangrene appeared in all the toes. There were never any symptoms on the left. He smoked twenty cigarettes daily. On investigating his past history, it was found that in 1929 a small receptacle struck his right great toe, giving him little or no pain. That evening the toe became red and two days later a blister formed, which developed into a discharging ulcer. A few days later the adjacent toe passed through a similar train of events. It took four months for these lesions to heal, and for one year afterward the right great toe became painful in cold weather. This patient presented a claim to the Industrial Accident Commission that his present condition was directly due to his employment and, therefore, compensable.

On examination the upper extremities were normal. The right lower extremity showed a dry gangrenous

process involving all the toes, and extended about one and one-half centimeters on the dorsum of the foot. There was a small ulcer on the inner aspect of the heel about one-half centimeter in diameter. The foot was markedly swollen to the ankle. No foot pulsations were felt. The popliteal pulsation was diminished. There was mild ischemia on elevation and mild rubor on dependency. On the left lower extremity the dorsalis pedis pulsation was diminished, otherwise the vessels were normal. The clinical picture was quite typical of an obliterating arterial disease, involving both lower extremities, especially the right. The further course of the disease confirmed this. About ten days after this examination the lower extremity was amputated at the junction of the upper and middle third of the leg, and pathologic examination showed a severe thromboangiitis obliterans. In the testimony before the Industrial Accident Commission it was shown that the discharges contained no irritating substances which could have been the factor in producing the original ulcer, and that his disability was the end-result of the progress of an underlying chronic arterial disease which had been present for several years, and which had no causal relationship to his employment.

COMMENT

Whenever there is delayed healing of wounds without apparent cause, a history of chronic ulceration or gangrene, or symptoms of arterial insufficiency, and especially when these are associated with objective signs of arterial disease, the patient should be given a complete vascular examination. By this is meant a careful clinical investigation, a carefully controlled test of the part played by the sympathetic nervous system, and tests for the state of collateral circulation of the skin, if indicated. Diminution of arterial pulsations, decrease in local temperatures, ischemia on elevation, rubor on dependency, trophic changes, discoloration, ulceration and gangrene, all give objective evidence of failing circulation. The surface temperature of the part is in direct proportion to the amount of blood flowing through it. By measuring the skin temperature, under controlled conditions, before and after paralysis of the vasoconstrictor fibers, one can determine whether the failure of the circulation is due to arterial occlusion, to pure arteriospasm, or to a combination of both. In the latter instance, one can determine quantitatively the relative proportion of each. Vasoconstrictor paralysis may be induced by various means. We prefer novocain block of the peripheral nerves, using the posterior tibial nerve for the feet, and the ulnar or median nerve for the hands. Whenever there is a question of the reference of pain over sympathetic pathways, the lumbar chain should be blocked directly.

In patients with occlusive arterial disease, the state of the collateral circulation of the skin may be estimated by the local response to intradermal injections of histamin. The lack of appearance of a flare indicates a poor collateral circulation, and warns against the use of such areas as covers for amputation stumps.

If arterial insufficiency is purely or predominantly spastic, the treatment is directed to ablation of sympathetic influence. Conservative measures are tried first, and if no relief is afforded, sympathetic ganglionectomy is to be considered. If the disease is predominantly occlusive, sympathectomy will give little relief.

Certain selected cases of occlusive disease are benefited markedly by ligation of the main vein

to the limb. Our experiences with a small series of cases has been gratifying.

It is felt that suction pressure therapy will have a definite place in the treatment of these cases, but one should be guarded in his prognosis of results until experience with this method becomes more general. In our sympathetic and vascular department, the results of suction pressure therapy have been somewhat disappointing.

IN CONCLUSION

It is hoped that the more general realization of the important part played by diseases of the peripheral arteries in many industrial injuries will lead to a greater coöperation between the industrial and the vascular surgeon, to the benefit of both the patient and the insurance carrier.

450 Sutter Street.

DISCUSSION

VERNON P. THOMPSON, M. D. (2007 Wilshire Boulevard, Los Angeles).—The first portion of Doctor Pearl's paper gives an excellent summary of the surgery of direct injuries to normal peripheral arteries. My discussion will be confined to the second phase of the paper—that of industrial accidents to individuals with preëxisting chronic arterial disease. It would be difficult to compile from any series of cases two more informative than he reports.

The rôle of industrial accidents in precipitating or aggravating symptoms, due primarily to preëxisting occlusive arterial disease, cannot be appreciated except on a basis of thorough clinical study of the circulatory phenomena present. Simple, direct, clinical observations are sufficient in the great majority of cases to establish the adequacy or inadequacy of the circulation.

Can the muscles do a reasonable amount of work without complaints or cramping? If so, the volume flow of blood through them is adequate. Are the feet and lower legs warm, capillary beds pink, the color remaining on elevation, returning quickly after pressure? If so, further encouraging information is obtained. Is the skin elastic, firm, and not atrophic, inelastic, or doughy and edematous? If, on the contrary, impairment of muscular activity, presence of blanching of capillary beds on elevation, poor nutrition of the skin, and muscular atrophy with persistent coolness are present, there is direct evidence of an inadequate blood volume flow to the extremities.

Data as to the various arterial pulsations present or absent, of calcifying changes in the x-rays, are obvious observations to make and record, but do not bear directly on the question of adequacy or inadequacy of the actual capillary blood volume flow. While detailing the more elaborate tests of determining blood flow, whether due to fixed occlusive processes, or due in part to vasospasm, Doctor Pearl has wisely emphasized the easily obtained clinical data which should shorten the waiting period of months, even years, between the onset of symptoms and the diagnosis.

EMILE HOLMAN, M. D. (Stanford University Hospital, San Francisco).—Experiences such as are recorded in Doctor Pearl's article, illustrate the necessity of careful physical examination of all applicants for positions in industry. Such physical examinations should consider not only the state of the heart and lungs, and the presence or absence of hernia, but most particularly the state of the peripheral vascular system. Absent pulsation in the dorsalis pedis and posterior tibial arteries need not necessarily preclude employment, but a record of an inadequate circulation would be of great help in case of subsequent injury. Moreover, even though symptoms are not present at the time, much can be done to avoid trouble if, in the presence of absent pulsation of peripheral arteries, certain instructions are given to the applicant. He should be warned against injury by ill-fitting shoes, by cutting corns and nails, and by frostbite. If injury does occur, precautions against infection should be carried out immediately: (1) by washing with soap and water; (2) by the application of

a mild antiseptic (not full-strength iodine); and (3) by the application of sterile dressing until healed. A known disability may be easily guarded against; but, if unknown, the loss of a limb may be at stake.

Similarly, in every complete physical examination by a consultant or internist, the state of the peripheral vessels must be recorded. If they are found subnormal or absent, instructions similar to the above may be of untold value to the patient in avoiding trouble. Inadequate circulation may be endurable and without danger if uncomplicated by injury or infection. If infection is added to the disability of inadequate circulation, a vicious circle may be set up which threatens life itself.

❧

WILLIAM J. KERR, M.D. (University of California Hospital, San Francisco).—There is little to add to Doctor Pearl's discussion. The basic principles of value have been stated, and although many details of the tests may be added, enough have been mentioned to help the clinician in the analysis of the problem in each patient. When patients with circulatory disorders present themselves, it has been most helpful for me to keep in mind the structures and their functions which are important in the maintenance of the normal circulation to these parts. First, comes a careful description and location of the lesions; then a study of all the arteries of the body available for examination as to size, consistency and patency, with pressures and quality and volume of pulsations. The veins and lymphatics should be surveyed also. The nervous system and osseous system may be at fault and should be examined carefully. It may be necessary to determine the element of spasm in the causation of symptoms, and this can be accomplished by the methods mentioned. Usually simple methods are most helpful. Histologic examination of tissues may be necessary and many special studies may be required to determine etiologic factors. When all methods of examination are completed and the cause of the circulatory disturbance has been found, the outlook from treatment is too often very disappointing. Very little result of a permanent nature can be expected by any method of treatment in the progressive degenerative and proliferating diseases of the arteries. The symptoms and signs which are stated to be characteristic of certain vascular diseases of the extremities are usually due to alterations of function, and may be due to many types of primary lesions. The problem in industrial medicine and surgery is a difficult one. We can expect that many patients with faulty arterial supply to the extremities may continue for extended periods without symptoms and, following slight injury, develop serious lesions rapidly. We recognize this principle when we urge great precaution in the care of the feet in the arteriosclerotic and diabetic patient. The problem of industrial hazard is the same as in the cardiac, tubercular, or arthritic patient.

Paralytic and Preparalytic Poliomyelitis.—According to a note in *Public Health Reports*, two states have already instituted a classification for reporting cases of poliomyelitis into paralytic and preparalytic or nonparalytic types. The Department of Public Health of Massachusetts placed this classification in effect at the beginning of the present year. Effective October 20, a similar division was to be reported in the state of Tennessee. The number of cases of preparalytic poliomyelitis which are included in the total reported for that disease will be stated in each weekly report. These are nonfatal cases of poliomyelitis that have not shown definite muscular weakness. Because of the variability and uncertainty in recognition of nonparalytic poliomyelitis, it is believed that for recording and comparing intensity of spread of poliomyelitis only the paralytic cases should be counted when such distinction is possible. Any notable number of nonparalytic cases will be reported separately. There is no intention in this procedure to minimize the importance of the preparalytic or nonparalytic cases from the point of view of the spread of the disease or the necessity for medical care.—*Journal of the American Medical Association*, December 12, 1936.

THE LURE OF MEDICAL HISTORY†

THE HUNTERS IN EMBRYOLOGY*

By A. W. MEYER, M.D.

Stanford University

III **

WILLIAM HUNTER deserves great credit for regarding the decidua as a growth of the lining of the uterus instead of a coagulum. It seems that the idea that it was a coagulum was attributed to William through the text of 1794 to the Gravid Uterus, written by his brother John and Matthew Baillie.³⁰ The idea hence became current as that of William instead of John, perhaps because the 1794 text appeared later and had a wider circulation than the famous atlas itself. It is noteworthy that even von Baer,³¹ in his observations on the development of man, which appeared in 1835, spoke of the Membrana decidua hunteri as a layer of unorganized secretion lying upon and between the elongated villi of the pregnant uterus. Von Baer thought the blood vessels invaded this layer, growing around the villi and forming so complete a plexus that he could not distinguish the arteries from the veins. He believed that this indicated that the relation of the decidua to the uterus is that of an inflammatory exudate to the injured tissues, and added that he hesitated to regard the human decidua as a "proliferation of the mucosa as Seiler recently had done, and shared the more generally accepted opinion that it is a coagulum." In discussing the idea further, von Baer brought together a number of facts which he believed supported a view also held by Purkinje³² (1834).[§]

It may have been fortunate that John was probably unaware of the views of "eminent anatomists" referred to by Haller on this matter, unless he could also have known what Aranzi³³ and others had thought, and what Falconnet³⁴ and

others had done, in order to solve the vexed problem of the utero-placental circulation. Concerning the controversy between the two, Teacher regarded the account of William more probable than that of John. One cannot contemplate the rejoinder of William to John, made to the Royal Society on February 3, 1780, without noting its evasion and ambiguity. It must be wholly unconvincing except to those to whom the possession of stolen goods is conclusive proof of their rightful ownership, for that is a form of reasoning resorted to by William. Moreover, one cannot help wondering what experience William had that caused him to declare to his students that "... most philosophers, most great men, most anatomists, and most other men of eminence lie like the devil." Moreover, it is well to recall William's words regarding the fetal and maternal portions of the decidua as quoted by Teacher⁹ (p. lvi), which are to the effect that the vessels of these two parts are separate because "those of the umbilical always 'remained uninjected.' 'It was this appearance,' he says (in his lectures of 1775), 'in the cat and bitch that first led me into the apprehension that the human placenta was the same. I thought this a long time, but I never cared to assert it openly till within these few years.'"

Scrutiny of the Gravid Uterus does not seem to bear out the statement of Bilikiewicz³ (1932) that William Hunter was the first to investigate the uterine and fetal membranes with the greatest thoroughness, and that he described them in every detail so as to satisfy the high exactions of contemporary anatomy. Bilikiewicz also spoke of numerous discoveries in the field of anatomy and the anatomy of pregnancy by Hunter, which affected the further development of theories of obstetrics and also those of embryology, but added that the text of the Gravid Uterus comprised the whole of Hunter's anatomic-obstetrical science.

PLACE OF WILLIAM HUNTER IN EMBRYOLOGY

When considering the claims of William to a place in embryology, it must also be remembered that the Gravid Uterus contains some drawings of relatively young human conceptuses; one on Plate 33 being what Hunter quite correctly called an "eight-to-nine-week embryo," for the specimen seems to belong to an 18-millimeter stage and hence is only a little younger. It is interesting that William thought that the decidua is expelled at birth and in abortion, and that he represented the yolk sac and knew of its presence in the mature placenta.

In addition to the above claims to remembrance in the history of embryology, William has others, however. One of the chief of these is the fact that he encouraged and financed William Cruikshank in his search for the mammalian ovum in the rabbit. That Cruikshank was unusually successful in this difficult task is shown by the fact that he obtained more than a score of such very young blastocysts that von Baer wondered why this fine accomplishment had not led others to anticipate his own discovery by many years. It is of special interest that the results of Cruikshank's investi-

Fig. 1.—The Reynolds portrait of John Hunter from the works of John Hunter, F. R. S., with notes, edited by James F. Palmer. Plates. London, 1837.

gations upon rabbits had, according to his own words, been incorporated for nineteen years, in the lectures at the Great Windmill Street School, before they were finally reported to the Royal Society in 1797, through the instrumentality of Sir Everard Home, John's brother-in-law.

William's third and strongest claim to remembrance in connection with embryology is the fact that he gave John the opportunity he sought, to join him at the School of Anatomy, and thus afforded him an opportunity to develop his interests in natural history. It seems that John was then an unlettered and untrained, even if not also a spoiled and uncouth orphan of twenty years. He had been a failure in life thus far, but was stimulated so deeply by the activities permitted him by his apprenticeship to William that he had undertaken investigations on generation by 1755. This was within a year of the time when he had the exceptional opportunity to study and dissect a human uterus with fetus near term, injected by McKenzie, and the occasion on which John apparently rediscovered the independence of the maternal and fetal circulations. It seems that the cadaver had been injected through the uterine, and the unborn child through the umbilical vessels, and John said that he conceived the idea of the independence of the circulations while dissecting the placenta. Although he later wrote that his elder brother received the idea with "raillery," when he broached it to him at the time, it is a well-known fact that William maintained that it was his own discovery, and that he always had incorporated the idea in the first and only public lecture in the fall of every year. Had William sponsored the idea of the independence of the two circulations before 1754, it is extremely un-

likely that John would have remained unaware of it, and he hence would have had no occasion to think that he had made a discovery when dissecting the female body injected by McKenzie and so report to William. Moreover, according to Paget,³⁵ the manuscript notes taken by one who attended William's lectures in 1755-1756 show "that William Hunter, even then, a year after the discovery of the placental structures, neither spoke of it nor understood the meaning of it."—the uteroplacental circulation. These words also are in complete accord with those quoted above from Teacher, and also those from the anonymous auditor apparently written after the death of William, and if true, fully confirm John's statement regarding William's reaction to the idea. Moreover, careful scrutiny of the text written by William himself for his famous folio, published in 1774, twenty years after John's rediscovery, confirms Paget's view completely, for the independence of the two circulations is only implied, not represented or asserted there. However, it is not my purpose to cast lots between two famous men, but merely to show that John has better claims than William to a place in the history of embryology.

JOHN HUNTER'S INTEREST IN EMBRYOLOGY

John's interest in embryology was so enduring that he was still appealing for ostrich eggs almost forty years after he began his studies in embryology, and the very year of his death. Evidence of this is contained in a letter written by him to a friend traveling in Africa at that time. Since he had received only two ostrich eggs in thirty years, this certainly is eloquent testimony to his interest in the subject. I have considered the claims of John alone to a place in the history of embryology more fully elsewhere* and, in addition to the things mentioned, attention may also be directed to the collections which he assembled upon the subject. According to Ottley,³⁶ these illustrate various phases of comparative embryology, both normal and abnormal, and comprise 1,500 preparations illustrating reproduction in both plants and animals. The collection on the development of the ovum is said to be represented by three series:

"First, in plants which have no evident seeds; next, in gemmiparous animals, as the hydatid; next, in cryptogamous and phanerogamous plants; and lastly, in hermaphrodite animals, whether self-impregnating, as the asteria, the barnacle; or mutually impregnating, as snails, slugs, and other gasterapods." A sixth series of over four hundred fifty specimens is said to represent "the various conditions in which the eggs of oviparous animals are placed for the purpose of being hatched, and of the changes which take place in the young animal during the foetal state." The seventh and eighth series of specimens are said to represent

"the development of the ovum and its contents in Mammalia," and "the principal peculiarities of structure in the young animal during the foetal state, such as the yolk bag, and its connexion with the foetus; the foetal circulation in birds; the horny knob on the beak used in breaking the shell; the reception of the yolk into the stomach; the umbilical cord in Mammalia; the open foramen ovale; the ventricles of the heart of equal thickness; the situation and descent of the testes; the membrana pupillaris, and the large thymus gland." The ninth series is said to illustrate the growth of the young in both plants and animals, and the tenth, "various modes in which food and protection are furnished for the young animal." There also are said to be specimens in abnormal development illustrating the "preternatural situation of parts" and "the addition of parts."

I do not know whether some of the specimens in this collection, which seem rather apocryphal, were prepared by John himself, but I have long been curious to see the head of a duck with a limb arising from it, and the case of the "double skull, which belonged to a child of six years of age. The skulls are united by their vertices; the upper one was supplied by blood vessels passing through the united portions; and from the account given by eyewitnesses, the upper head seems during life to have experienced sensations, and to have exhibited mental operations distinct from those of the lower head." When one recalls the report given John by an enthusiastic Philadelphian, of the frequency of the occurrence of double-headed snakes in America, and if one makes allowance for the early state of embryology at the time, it is not difficult to see that an enthusiastic collector and a very busy man such as John Hunter, may at times have been imposed upon. If so, the matter scarcely justifies cavil now, for there can be no doubt about John's scientific enthusiasm, and his experimental approach to the problems which confronted him deserves much praise. It seems to me that his abiding interest and his accomplishments in the subject of development greatly exceeded those of the so-called iconographers, and that in spite of the fact that the many fine illustrations on the development of the chick and goose remain unknown, John deserves a place in the history of embryology much more than his brother William, upon the basis of iconography alone. It is true that John never finished the text on the hen or the goose, but surely he is not alone in being found by Chronos with an unfinished task. Moreover, the writing of these texts would have been an unusually difficult task for one who lacked linguistic training. He might have encountered insuperable difficulties in devising new terms, regarding which he had said: "To coin new words would not answer the purpose, because then I must have a dictionary of my own." Certainly no finer tribute could be paid John for his conclusion regarding the independence of the uteroplacental circulation in 1754 than the belief of Haller, in 1767, that "eminent anatomists" had proved that the two circulations were one.

CLINICAL NOTES AND CASE REPORTS

ACUTE DIFFUSE GLOMERULONEPHRITIS*

By JESSIE M. BIERMAN, M.D.
San Francisco

HISTORY.—Case 56975: An eleven-year-old boy was the son of healthy parents and had been well, except for having measles, chickenpox and scarlet fever in mild form in early childhood. On December 17 he complained of sore throat and was feverish. He was put to bed and remained there for several days, after which he seemed perfectly well until January 5, when he complained of headache and his mother noticed that his face was swollen. The following day he vomited, and the swelling and headache became more marked. On January 8 he retained no food or fluids, and seemed very ill. Next day he suddenly complained of being unable to see and his head began to jerk. He soon lapsed into unconsciousness and was brought to the Children's Hospital on January 9.

Physical Examination.—He was a very well-nourished and well-developed boy, whose face was pale and very edematous. It was impossible to arouse him during the examination. Breathing was deep and quiet. The skin was warm and moist. The neck was not stiff. The pupils were equal and reacted to light. There were conjunctival hemorrhages in both inner canthi. The retinal vessels were of normal appearance. There were no hemorrhages or exudate. The breath had a uriferous odor. The teeth contained several small cavities. The gums were healthy. The tonsils were large and injected. There was no post-nasal discharge. Several small discrete glands were palpable in the posterior cervical regions. The pulse was slow, regular and bounding. The cardiac impulse was visible in the fifth interspace inside the midclavicular line. The area of cardiac dullness was not increased. Both sounds were clear and of good quality and rhythm. The blood pressure was 162 systolic, 108 diastolic. The lung fields were clear. The abdominal wall was thick and relaxed. The liver was not enlarged. The kidneys and spleen were not palpable. The percussion note was tympanitic over most of the abdomen. There was no flatness in the flanks. The extremities were relaxed. Slight pitting edema was present in both ankles. There was no desquamation of either the palms or the soles. The patellar, ankle, and plantar reflexes gave normal response, but were hyperactive. The rectal temperature was 96.4, the pulse 74, the respiration 18.

Shortly after the examination the boy aroused and complained of frontal headache. A small amount of amber-colored cloudy urine was passed. It was strongly acid, of a specific gravity of 1.032 and contained a heavy cloud of albumin (over one per cent), no sugar, a large amount of acetone, a trace of diacetic acid. After centrifugalization the sediment was found to contain seven to ten red blood cells, ten to twelve white blood cells, and two to five casts in each high dry field. The casts consisted chiefly of finely and coarsely granular forms, with occasional hyaline and red blood cells forms. The hemoglobin was 95 per cent with 5.9 M red blood cells. The leukocytes were 15,200 with 98 per cent polymorphonuclears.

Diagnosis.—The history of puffiness of the face and headache occurring about three weeks after sore throat suggests at once the diagnosis of acute nephritis.

The delay in appearance of symptoms after the acute infection, the non-dependent edema, the rise of blood pressure, the early appearance of cerebral symptoms and the small amount of blood in the urine, speak for acute diffuse glomerulonephritis, with eclamptic symptoms (Vollhard-Fahr), as against focal nephritis, in which usually gross hematuria appears during the course of acute infectious diseases, and is not likely to be accompanied by more than slight hypertension and edema.

The history of scarlet fever previously and the absence of rash with and of desquamation following the sore

throat preclude this as a cause of the trouble; although postscarletinal nephritis often takes this form. That we are not dealing with chronic glomerulonephritis with uremia is indicated by the history of previous robust health, lack of anemia, normal heart contour and sounds, high urinary specific gravity, normal eye-ground findings, and the eclamptic type of cerebral symptoms, as contrasted with the slowly developing asthenic uremia of failing kidneys. Other causes of convulsions and coma, such as cerebral injury, diabetes, encephalitis, epilepsy, are easily ruled out.

Progress and Treatment.—Ten cubic centimeters of 25 per cent solution magnesium sulphate was given intramuscularly shortly after admission. This was followed by an intravenous injection of 150 cubic centimeters of hypertonic (25 per cent) glucose solution. A few hours after regaining consciousness, irregular nystagmus and clonic convulsions of the neck and face muscles began. This was followed by involvement of the right arm and leg, and became generalized after ten minutes. The blood pressure rose to 180/140. Three grains of sodium phenobarbital was given intramuscularly, and two more intramuscular injections of magnesium sulphate, at hourly intervals. The blood pressure dropped to 136/100 at the end of two hours, and convulsions ceased. The following morning the blood pressure was 160/110, the patient was conscious and fairly comfortable. The blood pressure gradually rose, and as it reached 174/120 twitching began. By noon it had reached 198/120, the patient was unconscious and convulsing severely. After large doses of magnesium sulphate, given both intravenously and intramuscularly, the blood pressure fell to 146/98 and convulsions ceased. The next day he was much better in every way. The blood pressure did not rise above 160/106, and headache and nausea had disappeared. Magnesium sulphate was continued by mouth until the fifth day, when the blood pressure had reached 100/70 and all edema had disappeared. The diet consisted of milk, fruit juices freely, vegetables, and restricted salt.

The blood nonprotein nitrogen, taken upon entry while the patient was unconscious, was 37.5 milligrams per 100 cubic centimeters.

An Addis count performed on a concentrated twelve-hour specimen of urine, done a week after entry, showed: Volume, 250 cubic centimeters—acid; specific gravity, 1.028; albumen, 3 per cent (Esbach); red blood cells, 8,265,277 (normal, under 500,000); white blood cells and epithelial cells, 901,388 (normal—under 2,000,000); casts, 61,111 (normal—under 5,000); 50 per cent granular—25 per cent red blood cells and 25 per cent hyaline.

Subsequent Addis counts showed gradual decrease in red blood cells, casts, and albumen.

The patient was dismissed on January 30 and has since been followed in the out-patient clinic. At the last examination, done ten months after onset of the nephritis, the blood pressure was found to be 110/75; the hemoglobin 85 per cent, with 4.5 M red cells. The Addis test showed: Volume, 250 cubic centimeters—clear, amber, acid; specific gravity, 1.031; no albumen (qual.); red blood cells, 2,497,000; white blood cells and epithelial cells, 519,000; casts, 27,750 with about equal numbers of red blood cells and finely granular casts. A number of routine urine examinations, done by the clinic laboratory, had been reported normal.

Prognosis.—The matter of complete recovery from acute diffuse glomerulonephritis in childhood is a subject of considerable difference of opinion among various observers. Undoubtedly many cases have been dismissed in the past as cured because careful quantitative studies of the urinary sediment under proper conditions have not been done. It is notable that, in this case, after ten months the output of red cells in the urine is still considerably above normal (500,000), yet their presence was missed in a dilute specimen of urine examined in the usual routine way. The presence of red blood cell casts is further indication that healing has not taken place. The high specific gravity denotes good functional ability.

The disease is now in the latent stage, and there is about an even chance that all traces of activity will subside within three years after the onset. If healing does not take place within this time, little chance for ultimate recovery can be anticipated.

384 Post Street.

*From the Department of Pediatrics, Children's Hospital, San Francisco.

MEDULLOBLASTOMA*

REPORT OF CASE

By EDWARD LEEF, M.D.
San Francisco

THE case we are presenting is of medulloblastoma in a girl of seventeen, first seen by us October 17, 1930, and still living. The purpose in presenting this case is to emphasize the need of thorough roentgen treatment to the entire cerebrospinal system, following decompression and removal of all or part of the tumor.

NATURE OF MEDULLOBLASTOMA

Medulloblastoma is one of the gliomata in which the cells represent an embryonic stage earlier than either the spongioblast or the neuroblast. These are rapidly growing cellular tumors occurring most frequently in children, in the central part of the cerebellum, usually arising from the roof of the fourth ventricle. This type of glioma frequently invades the subarachnoid spaces; and after operative removal of the primary tumor, there are likely to be implants along the spinal region. Bailey and Cushing¹ first described these tumors in 1925, presenting twenty-nine cases. They describe the microscopic appearance of these tumors as being composed of rounded, or pear-shaped, sometimes spindle-shaped cells with scanty cytoplasm and big oval nuclei containing an abundant network of chromatin. The cells appear as a loose structureless mass, but the nuclei occasionally arrange themselves in pseudo-rosettes or lie in strands. The case which we are reporting may be described as a very cellular tumor with the cells divided into groups by fibrous stroma. The cells have a moderate amount of cytoplasm and large, round, granular nuclei, a number of which show mitotic figures. The tumor is quite vascular and in places tumor cells are found invading the blood vessels (Figs. 1 and 2).

* Read before the Cancer Commission of the California Medical Association at its conference at Yosemite, May 12, 1935.

TREATMENT

In treatment, authors are agreed that the medulloblastoma is quite susceptible to radiation; that suboccipital decompression should precede irradiation, and that normal brain tissue is not injured by irradiation.

Bailey and Cushing,¹ in the cases reported in 1925, found that those that survived the operation and were not treated (nine cases) had an average survival of seven months; while those treated with radiation, including only those who have died (ten cases), had an average survival period of nineteen months.

Bailey, Sossman, and Van Dessel,² in 1928, reported eleven cases and found that roentgen treatment retarded the growth of the tumor, so that the average survival period of the treated cases was thirty-four months.

Bailey,³ in 1930, reported four such patients who received more thorough treatment than any of the others. He found that recurrence of the symptoms, with ultimate fatality, was the rule. Each of these patients was given several courses of deep therapy over the entire brain and spine.

Cushing,⁴ in 1930, reported sixty-one cases, thirty-one of which received x-ray therapy in varying amounts from one to twenty courses. The average survival period of these patients was fourteen months, one patient living as long as five years and three months before death.

Tracy and Mandeville,⁵ in 1931, reported three patients improved by x-ray therapy. They advised thorough deep roentgen therapy over the entire cerebrospinal system following operation, repeating the cycle two to four times during the first year.

Fig. 2.—High-power photomicrograph. This shows the large round granular nuclei.

Brody and German,⁶ in 1933, reported fifteen cases in six of which the patients received intensive radiation to the entire cerebrospinal system, and five of whom were still living with an average duration of twenty months.

REPORT OF CASE

We have had several cases of medulloblastoma, but the case which we are reporting is Miss E. S., age 17, whom we first saw October 17, 1930. At that time her complaint was pain and numbness in the left leg, followed by loss of strength in it during the last week. The pain, severe cramp-like in character, started suddenly in the outer aspect of the left leg and spread to the whole leg, thigh, and foot. After a week's rest in bed the patient felt less pain, but the left leg felt numb and became progressively weaker until finally the limb became paralyzed. It was in this condition that the patient entered the hospital.

The past history was not important.

Examination of the patient showed a young girl without any complaints excepting those mentioned before. She was pleasant, bright, and did not appear to be seriously ill. All systems were normal excepting the nervous system, and here we found several pathologic changes.

Brudzinski's and Kernig's signs were positive on the left side.

Knee-jerks were absent on the left side.

Ankle-jerks were absent on both sides.

Babinski's sign was positive on the right side.

There were diminished abdominal reflexes on the left side.

There was parasthesia over the left leg and thigh.

There was hyperesthesia over the right leg below the knee.

There was flaccid paralysis of all of the muscles of the left foot and toes, and partial paralysis of the muscles of the left leg and thigh.

There was no involvement of any of the cranial nerves.

There was no evidence of increased intracranial pressure.

The clinical diagnosis during this time was the paralytic stage of anterior poliomyelitis. However, weakness became progressive until October 30, 1930, when both the right and left lower extremities had become totally paralyzed. Then, on November 1, 1930, a spinal puncture was done and no fluid obtained. A combined cisternal and lumbar puncture on November 4 showed clear cisternal fluid and, with pressure, a few cubic centimeters of yellow spinal fluid was obtained. At the same time 1.2 cubic centimeters of lipiodol was injected into the cisterna. This lipiodol descended only as far as the upper level of the third lumbar vertebra (Fig. 3). On November 6, 1930, Doctor Reichert did a laminectomy, and upon opening the dura he found a tumor extending from the third to the fifth lumbar vertebrae. The tumor was dissected free and removed. After this there was a gradual return of the reflexes to normal or toward improvement. Deep x-ray therapy was given starting the twelfth day after operation, the lumbar spine receiving 600 r, both anteriorly and posteriorly, in four days.

On November 23, 1930, the patient was sent home, being much improved. By February 26, 1931, she was walking fairly well. By June 3, 1931, she was able to walk and dance well. On June 4 the patient was started on another four-day course of deep therapy, 200 roentgens being given each day to the lumbar spine posteriorly.

The patient got along quite well and was not heard from until October 27, 1931, when she returned complaining of some disturbance in vision, pain between the shoulders, and parasthesia in both arms. Deep x-ray therapy was given again, this time to the cervical and upper dorsal spine, 200 r daily, alternating anteriorly and posteriorly for ten days. After the third treatment all symptoms had disappeared.

December 2, 1931, the patient returned again complaining of headache and dizziness, and vomiting of ten days' duration. Examination showed no disturbance of the cranial nerves, and the reflexes were unchanged. The

Fig. 3.—This shows the lipiodol stopped at the level of the third lumbar vertebra.

following day Doctor Reichert did a suboccipital decompression and exploration. This disclosed the fourth ventricle infiltrated with tumor, about half of which could be removed. The postoperative course was stormy. On December 29, 1931, autopsy and undertaker permits were signed by the father. Deep x-ray therapy, having been started December 17, 1931, was being applied at this time. These treatments were given daily to the head, alternating right and left, 100 to 125 r each time, for twenty-two days.

A few of the progress notes at this time are as follows: December 12, 1931, the patient lies in a stupor, does not respond.

December 17, condition unchanged.

December 24, the patient is not quite so drowsy.

December 29, condition grave.

January 4, 1932, more alert, able to see.

January 12, talks intelligently and is enthusiastic.

January 17, up in a chair.

January 18, walked a few steps.

January 21, dismissed; walking with help.

Later, because there was a region of the cord still untreated, the patient was given another course of deep therapy to the middle and lower thoracic region. Treatments were given posteriorly for seven days, 150 r each time.

June 4, 1932, the patient again returned, this time complaining of occasional vomiting and blurring of vision in the right eye. Deep therapy was given to the cerebellar region, 100 r daily for two weeks. Improvement was definite by the end of the course, and when she returned for a check-up three months later she was feeling fine. On January 17, 1933, the patient reported again, stating that she had danced all but three dances on New Year's eve.

Further observations were made during 1933 and 1934. She felt well, except that the menses had not returned.

She was seen for the last time in June, 1935, feeling well as before. She told us she was getting married shortly.

CONCLUSION

This case is similar to some reported by others.

1. The tumor was widespread.

2. The tumor was radiosensitive.

3. Irradiation covered the brain and spinal cord. Stanford University Hospital.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

CONVULSIONS IN CHILDREN

I. ETIOLOGY

ROLAND P. SEITZ (490 Post Street, San Francisco).—The increased irritability of the nervous system plays an important part in the frequency with which convulsions occur. According to Morse,¹ the higher cerebral centers, inhibitory in action, are yet imperfectly developed and are thus less able to restrain discharges from lower centers than when perfect development occurs.

Heredity is likewise predisposing, and convulsions are infrequent in families with a stable nervous background. The clinician notes evidence of nervous disease in the parents of convulsive children with striking regularity; or one parent discloses that similar attacks occurred often in his or her childhood.

Excepting the first month of life, the commonest cause of convulsion is acute infection and this precipitates about a third of all attacks during childhood.

In the neonatal period most convulsions are on an organic basis associated with cerebral birth injury or intracranial hemorrhage. Recent reports indicate that not a few at this early age are due to tetany or spasmophilia. Proved cases show a serum calcium of 7.5 milligrams or less per 100 cubic centimeters of blood; probable cases respond to the administration of calcium salts. Acute infection and sepsis are not rare, and the navel may be the portal of entry.

Both Peterman² and Brown³ have recently presented statistical studies of the etiology of convulsions in childhood, and their results appear in Tables 1 and 2 respectively. Comparison is interesting and shows notable differences.

Acute infection is most often respiratory; but sepsis, pyelitis, otitis and the contagious diseases are commonly the exciting cause. Enteritis is usually infectious and most often encountered in

TABLE 2.—*The Incidence of Convulsions Among 400 Children (After Brown)*

Diagnosis	Number	Per Cent
Acute infection	120	30

the first six months of life. Some individuals have a low temperature threshold, and will manifest nervous symptoms regularly with a temperature of 102, while others are little affected in this regard by true hyperpyrexia.

Acute disease of the central nervous system with convulsions is most often meningitis. The B. influenzae, pneumococcus and streptococcus hemolyticus are repeatedly obtained on culture of the spinal fluid. Meningococcic meningitis, tuberculosis and syphilis are more rare. Other diseases will include encephalitis, plumbism, poliomyelitis and tetanus.

What of epilepsy? Is it true that every child who has a convulsion is a potential epileptic? It is well to remember that the convulsion in epilepsy is not accompanied by any visible pathological features and it occurs most frequently between the ages of 5 and 10 years. The epileptiform convulsion is transient, impairs or causes loss of consciousness, and must ultimately result in some change in the personality of the patient. Morse¹ followed a series of private patients in whom he had witnessed one or more convulsions for as long as twenty years. He concludes "most positively, there is no way to determine immediately when a baby or child has convulsions or repeated attacks suggesting petit mal, whether it has epilepsy or whether it will develop it later." He also affirms that the presence of an apparent cause for an attack does not, however, exclude epilepsy and this should not be forgotten. Hosen⁴ claims general statistics compiled by neurologists show that 22 per cent of the cases of infantile convulsions later develop epilepsy as compared to the pediatrician's 7 per cent.

Reflex convulsions must be almost negligible in spite of fanciful medical and lay beliefs associated with worms, teething, phimosis, et al. The ob-

scure case may require, in addition to the usual examinations and laboratory work, special investigation of the blood chemistry, dextrose tolerance tests, examinations of the spinal fluid, encephalograms, examination of the fundi, roentgen examinations, and yet remain undiagnosed after months of observation.

* * *

II. SYMPTOMS AND DIAGNOSIS

ARTHUR A. BIRD, M. D. (3022 East Fourteenth Street, Oakland).—Symptoms of convulsions have a wide range in severity, power, and amplitude.

The mildest is a momentary lapse of activity, a staring away into space for a few seconds or a partial closing of the eyelids, with resumption of activity where it was left off.

This has been designated an "absence," but can be so persistent in recurrence as to constitute a major disabling condition.

A single muscle or local group, one side of the body or the entire voluntary muscular system may participate, almost always with loss of consciousness.

The eyeballs will usually rotate upward and outward, to left or right; the pupils be dilated, unequal, reacting sluggishly to light, or not at all until the paroxysm is about over.

More or less back, neck and head bowing occur with cyanosis from reduced breathing rate and closing of epiglottis consequent upon the muscular rigidity.

The usual sequence is a sudden stiffening or tightening of the body, held so for some seconds as tonic part or phase. This is then followed by the intermittent relaxation and tightening or jerking phase, the clonic movements.

The time element may be from one minute to twenty minutes or more, and the frequency may be a single one or become almost continuous as in status epilepticus.

The diagnosis is rather apparent, but may take days to complete the differential. This lies in determining whether it is central or from acute infection, toxic from so-called absorption, uremic, which is doubtful or tetanic with Chvostek's sign, and carpo-pedal spasm.

It may be, but is usually not epileptic, occasionally eclamptic in type in very young infants.

* * *

III. TREATMENT

HUGH K. BERKLEY, M.D. (1136 West Sixth Street, Los Angeles).—It is obvious that the treatment of convulsions in children must vary between wide limits because of the wide variations in the causative factors. Similar treatment could not apply to the convulsions due to high fever and the convulsions of tuberculous meningitis.

Our discussion of treatment must, therefore, be more general than specific. Specific treatment can only be intelligently instituted after a complete study of a given case and the discovery of the etiological factors involved.

For the convenience of discussion we have adopted the following classification:

1. Immediate treatment.
 - (a) During the convulsion.
 - (b) After the convulsion.
2. Prophylactic treatment.

Immediate Treatment:

The majority of convulsions occurring in childhood are those of febrile origin; that is, convulsions occurring as an accompaniment to the high temperatures associated with the various acute illnesses of childhood. In this type of convulsion the character of the infection plays little part either in the duration, the severity or the treatment. Here the essential factors involved are the effects of a high temperature upon an unstable nervous system. Many children are so nervously constituted that a convulsion regularly occurs when their fever passes their convulsive threshold.

These convulsions are self-limited and will usually cease in a short time, even if untreated. When treatment can be instituted it should be directed toward lowering the temperature. Satisfactory methods of accomplishing this during the attack are hot baths or hot packs, ice bags to the head, or tepid sponges of water or alcohol. With the resultant drop in temperature the convulsion usually terminates.

If unusually severe or prolonged, a few whiffs of chloroform may be of advantage. Such a procedure is rarely necessary, and if required should make one suspect that the fever alone is not the cause of the convulsion.

After the convulsive seizure has stopped, other more effective antipyretic measures may be employed. The outstanding drug for this purpose is aspirin. This drug is almost universally well tolerated, even by very young children, and is very effective in its antipyretic properties. The dosage should be large enough to be effective.

To raise the convulsive threshold, sedatives may be given in addition to aspirin. The following drugs are usually effective: sodium bromid, barbiturates, magnesium sulphate, morphin and chloral hydrate. These are named in the order of choice.

As soon as these measures have been carried out, it immediately becomes the duty of the physician to ascertain the cause of the fever and institute such remedial measures as are appropriate for the infection found to be present.

Prophylactic Treatment:

To know which child will be subject to convulsions and which will not is, of course, impossible. When, however, a child has established his tendency in this direction by having a convulsion, it may be fairly predicted that he will have others under similar circumstances. It seems wise, therefore, to so inform the parents and clearly outline to them the measures to be taken at the onset of fever. By the early and proper use of antipyretics and sedatives many of these children may be safely guided through their febrile disturbances without further convulsions. With each year of

added age the tendency to convulsions becomes less marked, and after the tenth year they are comparatively rare even though sedatives are not used.

For those convulsions which are not produced by fever the procedure employed must vary with the various etiological factors involved. In this group the convulsions of epilepsy occupy the major position. The immediate treatment for the epileptic consists in getting the patient into a safe, comfortable position. Clothing should be loosened, and some firm but pliable object placed between the teeth to prevent the subject injuring his lips or tongue by biting. It is usually unnecessary to stop the convulsive seizures of epilepsy—they are self-limited. The prophylactic treatment of epilepsy is so complicated, and involves so many factors that it is without the scope of this discussion.

The convulsions occurring in the course of the various forms of meningitis are usually due to the cerebral irritation of the infection itself or the pressure produced by it. Pressure can be controlled by lumbar punctures at such intervals as are found necessary. In cases of spinal blocks, resort may be made to cisternal punctures. When the convulsions are due to meningeal irritation rather than to pressure, the barbiturates furnish a satisfactory solution in most instances. Dosage should be sufficiently large to produce the desired effect. In some few cases where a fatal result is certain, the use of morphin is highly satisfactory.

It is now well known that some convulsive seizures in children are due to a functional hypoglycemia. If the blood sugar has been established to be below 60 milligrams per cent during or at the end of a convulsion, hypoglycemia may be considered as a possible causative factor. In such instances glucose intravenously produces spectacular relief. As an emergency measure epinephrin by hypodermic injection will be effective until glucose may be given.

On occasions convulsions will occur with the more severe paroxysms of whooping cough. Usually such convulsions are due to anoxemia and are relieved by removing the obstructing mucous. Gagging the child by the finger to produce vomiting is often effective. Inverting the child may relieve the obstruction by gravity. Such cases, fortunately, are very rare.

In the convulsions of accidental strychnin poisoning, and the convulsions of tetanus infection, the barbiturates are usually effective. The intraspinal or intramuscular use of magnesium sulphate is effective. Dosages should be accurately computed by body weight.

A convulsive seizure in a child is a terrifying thing to the parents or relatives. To the physician it should be indicative of a severe illness, but not terrifying. At few times in a physician's career is it so necessary to remain calm and collected, and to impart this attitude to those around him. His calmness is most essential, and in many instances it is the most effective treatment for those primarily and secondarily involved in such trying circumstances.

Insecticide Makers Punished for Labels Lacking "Inert."
The failure of manufacturers to place on the labels of their products the ingredient statement required by the Federal Insecticide Act formed the basis of the majority of prosecutions recently terminated under that statute, the Food and Drug Administration reports. The Act provides that if a preparation contains an ingredient inert against insects or fungi, the label must bear an ingredient statement. The manufacturer has the option of stating upon the face of the principal label of an insecticide, fungicide, or disinfectant, either the name and percentage amount of each and every inert ingredient contained therein and the fact that it is inert, or the name and percentage amount of each and every active ingredient, together with the total percentage of inert ingredients.

After a plea of guilty, the Huntington Laboratories of Colorado, Inc., Denver, Colorado, was fined \$150 for shipping in interstate commerce a misbranded disinfectant called "San-Pheno." The preparation contained more than 65 per cent of water, and the label failed to bear the ingredient statement required by the Insecticide Act. The product was represented as being positive in bactericidal action and high in germicidal strength, and was recommended for disinfecting purposes, including the disinfection of surgical instruments. It was ineffective when used as a disinfectant at the dilutions specified. This was considered particularly serious where the product is used in operating rooms for the disinfection of the hands and surgical instruments, since the failure to disinfect under these circumstances is a source of potential danger of infection to the patient.

The Coöperative G. L. F. Mills, Inc., Buffalo, New York, pleaded guilty to two informations charging violation of the Insecticide Act in the misbranding and adulteration of "G L F Copper Lime Dust" and misbranding of "G L F Lime Sulphur Solution." The latter product contained more than 68 per cent of water, and the label bore no ingredient statement. The Copper Lime Dust fell below the professed standard and quality under which it was sold, containing less than the 15 per cent of calcium arsenate claimed on the label. A fine of \$150 was imposed. . . .

Two moth preparations, "Aroma Moth Vaporizer" and "Termox Mothproofing Crystals" were the subject of a criminal prosecution against Ben Berg and Sol Nathan, trading under the name of the Berg and Nathan Sales Company, Chicago, Illinois. The "Aroma Moth Vaporizer" consisted of less than 2 per cent of paradichlorobenzene and more than 98 per cent of sodium chlorid (common salt), an inert ingredient not stated on the label, and was recommended for the control of moths in closets, trunks, dresser drawers, and garment bags, and for packing away furs and blankets. It was ineffective for the control of moths. The "Termox Mothproofing Crystals" contained about 60 per cent of common salt, and no ingredient statement appeared upon the label. A plea of guilty was entered and a fine of \$25 imposed.

Primary Streptococcic Peritonitis.—Analysis of forty-two cases of streptococcic peritonitis leads Pollock to believe that the condition can be readily recognized in most instances when it is recognized that it is seen most frequently in infants, that it is usually preceded by pharyngitis, that the abdominal symptoms, early distention and constant pain and tenderness, are generalized and start from two to three days after the subsidence of the infection of the respiratory tract, and that the condition is definitely diagnosed by abdominal puncture, the Gram-positive streptococci with pus cells being pathognomonic. The treatment depends on the severity and stage of the illness, each case being a rule unto itself. The mortality, at its lowest, is 80 per cent. The frequent severe sepsis interdicts early operation, while the peritonitis is generalized. In the interim, a continuous intravenous drip of saline solution, repeated transfusion of blood and the injection of pooled antistreptococcus serums is indicated. Laparotomy is valueless and even dangerous when the sepsis is severe. However, when the general infection is not marked and there is evidence of much peritoneal fluid, improvement is often observed when drainage is obtained by the simplest and most rapid means. The large walled-off abscesses should be drained.—*Archives of Surgery*, October, 1936.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6.

ASSOCIATION ACTIVITIES

AMERICAN MEDICAL ASSOCIATION SECRETARIES' CONFERENCE

In the last issue a summary of the address delivered to the conference by Surgeon-General Parran was published. That summary was sent by air mail to the printers. That issue went to press before the conference ended. A general summary will now be made.

The conference was opened by Chairman Rock Sleyster of the Board of Trustees. He traced the physical expansion of the Association during the past twenty-five years and closed by describing the remodeled headquarters building. During the past year a quarter of a million dollars was expended in remodeling. This expenditure has provided a very satisfactory exterior and interior that is a credit to the profession.

President Gordon Heyd of New York cited certain epochs in the history of medicine. He ascribed the survival of medicine through the ages and through changing times as being due to our ability to organize. The medical profession must concern itself with research and discoveries and then must see that its knowledge and resource obtain the widest possible distribution for the good of all people in all divisions or classes of society. He ended by stating that no matter what schemes, plans, or agencies were created, the providing of medical care would continue to require personal communion with a physician.

Malpractice suits and insurance was discussed. The increases of these suits were reported throughout the country. State organizations employ various means to protect its members.

In Chicago, newspaper editors were induced, by threats of suits for libel, to refrain from printing items that reported the initiation of a malpractice suit against a doctor. One out of every twenty physicians will be sued this coming year because of lucrative returns that lawyers

obtain from this racket. The possibility of being a defendant is ten times as great as having a fire in a doctor's office. The principal factor that inspires such suits is the criticism by a doctor of the treatment or services rendered by another doctor. In spite of almost constant warnings this breach of conduct continues, and until the time arrives when medical men desist making adverse comment, malpractice suits will continue to harass practitioners.

The American Medical Association trustees have determined to discontinue the publication of the *Monthly Bulletin*. A new department will be created in the *Journal of the American Medical Association* for the dissemination of association news.

The operation of the Michigan Filter System was described by the secretary of that state. The plan is coordinated social service that determines an individual's eligibility for charity services.

Dr. Glenn Myers of Los Angeles, by invitation, presented the plan of organization and operation of the California Public Health League. An interesting discussion was engaged in.

Mr. Holloway of the Bureau of Legal Medicine and Legislation discussed basic science laws and reviewed the effects of this form of legislation. California, New York, and Michigan are planning to obtain this form of legislation that is now in effect in eleven states. More will be said on this subject when our special committee presents its report.

A resolution was adopted urging that all state journals be protected by copyrights so as to prevent "throw away publications" from "lifting" scientific articles which, in the main, constitute the reading material in these pseudo-medical journals.

Warning was given that unless physicians were more careful in observing and complying with the federal narcotic laws that new legislation would be enacted that would be more rigid and would enforce greater restrictions to the embarrassment and inconvenience of practitioners.

Because of increasing correspondence, now tremendous in volume, the Bureau of Legal Medicine and Legislation has been compelled to restrict its services. Hereafter correspondence relating to legal and legislation questions will only be conducted through state secretaries. Individual members and county societies are urged to present their questions and problems to the secretary of their state organization and refrain from writing to the American Medical Association Bureau.

The value of these conference have been established. They afford an unusual opportunity to gain first-hand information and ascertain the functionings of sister state organizations. This year there was a universal sentiment that medicine must adapt itself to changing conditions and aid in molding federal and state plans for medical care for dependents along lines that will be acceptable to medical practitioners. Each state and each large metropolitan area must assume and meet their particular health and medical problems in a way that is best suited for each commonwealth. No one has as yet devised a satisfactory general national or state plan for the providing of medical care for indigents or those having low incomes.

The conference this year was a valuable one.

SYPHILIS

In joining the campaign to combat the prevalence of syphilis, it is suggested that county societies give consideration to gathering certain essential information as a basis for establishing a campaign program to be conducted under the supervision of members in joint effort with health departments.

*All articles listed under this caption, "This Month's Topics," have been written and sent to the Editor by the Association Secretary, Dr. Frederick C. Warnshuis.

Diagnostic Facilities

1. Are the services of laboratories ample for "dark-field," blood, and spinal fluid diagnosis?

1a. What recommendations?

2. What clinic facilities are available for treatment of individuals unable to obtain the service of private physicians?

2a. Recommendations as to establishment of such clinics?

3. Are you prepared to transmit to your members a minimum standard of treatment? How?

4. What recommendations as to the holding of clinics for instruction of physicians?

5. How do you propose to educate the lay public?

6. Have you conferred with the local health departments?

6a. Did you arrive at a mutual understanding and agreement?

6b. Did you agree upon fees for services rendered in public clinics?

6c. Did you agree on plan for providing free medication for indigents treated in your office?

6d. Did you agree upon report and record forms.

7. What plans were made for consultation services?

7a. For consultation by specialists?

8. What special problems or difficulties exist due to conditions peculiar to your county?

9. What plans do you recommend for case finding?

10. What plan do you recommend for control of patients who are in the infective stages, and how do you propose to control delinquency?

These are primary fundamentals to be considered and answered by every county society ere their local methods are inaugurated. Assistance and advice will be available through the State Secretary from the following Special State Committee:

Howard Morrow, Chairman, San Francisco.

Charles W. Barnett, San Francisco.

William Henry Goeckerman, Los Angeles.

* * *

The following letters from Surgeon-General Parran are informative.

November 30, 1936.

To the President, California Medical Association.

This will confirm the verbal request which I made to the presidents and secretaries of each state medical society in Chicago on November 16.

I would request that your State Medical Society appoint a committee to advise with your State Health Officer and with me regarding the syphilis control program in each State. Specifically it is my hope that this committee will (a) review the available information on the syphilis problem in the State; (b) cooperate in assembling necessary additional information concerning the nature and extent of the facilities which now exist for the diagnosis, treatment, and public health control of syphilis; and recommend such supplemental and new State and local facilities and measures as seem desirable in dealing with this infection which is nation-wide in its importance and distribution.

As illustrations of the many questions which need careful consideration from the viewpoints of both physician and health officer, I have attached several which will probably come up for discussion during the national conference mentioned below.

Since the Public Health Service is having a national conference on venereal disease control December 20 to 30, it is hoped that I may have a preliminary report from your committee before Christmas in order that the various suggestions which are received can be incorporated in the deliberations of the conference.

Sincerely yours,

(Signed) THOMAS PARRAN,
Surgeon-General.

* * *

QUESTIONS FOR SOLUTION IN SYPHILIS CONTROL

1. The system of notification most suitable to physicians, patients and health agencies.
2. The additional laboratory facilities needed for diagnosis of syphilis.
3. The policy recommended in the distribution of anti-syphilitic drugs.
4. The adequacy of free treatment facilities for those who cannot pay physician's fees.
5. The nature and extent of the additional facilities needed.

6. The physician's part in the application of epidemiologic methods for the control of syphilis.
7. The possibility of developing minimum standards of treatment for early syphilis.
8. The availability of hospital beds for treatment of cases needing hospitalization.
9. Methods for the more adequate prevention of congenital syphilis through recognizing and treating the disease among pregnant women.
10. The lines along which informative and educational programs should be conducted.
11. The possibilities of prophylactic measures being taught and administered through physicians' offices, out-patient hospital services and clinics, with the thoroughness and precautions governing Army and Navy procedures.

TREASURY DEPARTMENT
PUBLIC HEALTH SERVICE
WASHINGTON

December 9, 1936.

Dr. F. C. Warnshuis,
Secretary, California Medical Association,
Four Fifty Sutter,
San Francisco, California.

Dear Doctor Warnshuis:

I thank you for your very kind letter commenting upon my statements at the recent meeting of the Secretaries' Conference in Chicago, and for your offer of cooperation on the behalf of the California Medical Association.

Perhaps I did not make sufficiently clear in my address before the conference in Chicago what I had in mind with respect to recognizing and working through existing agencies in carrying out the expanded public health program which has been made possible under the provisions of the Social Security Act. What I intended to convey was that the Public Health Service will not itself carry on the work within the states, nor will it dictate to the states what the programs shall be or how they shall be conducted. It has been and will continue to be the policy of the Public Health Service to leave largely to the discretion of the several state health authorities the determination of what activities shall be carried on with the federal funds in each state and what methods shall be followed in carrying out such activities.

Social Security funds for assisting the states in public health work are allotted and paid to the state health authorities. The law stipulates that payment may be made only on the basis of plans submitted by the state health authorities. It would, therefore, be impossible for the Public Health Service to enter into any agreement with a state medical society under which such society might become the agency for receiving the funds allotted to the state for conducting the work. Plans for a number of projects have already been submitted by your state health officer, Doctor Dickie, and have been in operation for several months.

However, as I stated in my address in Chicago, the Public Health Service welcomes the cooperation of the state medical societies with their respective state health authorities in studying the health problems and the particular needs of each state, in planning the programs to meet these needs, and in carrying out such measures as may require the participation of the private physician in the actual conduct of the work. I am very much pleased to know that the California Medical Association stands ready to cooperate with Doctor Dickie and, through him, with the Public Health Service, in this great work.

Very sincerely yours,

(Signed) THOMAS PARRAN,
Surgeon-General.

COUNTY SECRETARIES' ANNUAL CONFERENCE

The annual conference of county secretaries, state officers, councilors, and county society presidents will be held at 9 a. m., Saturday, February 6, 1937, in the Sir Francis Drake Hotel in San Francisco.

The following program, Council approved, will govern this conference.

MORNING

9:00-9:10—Opening Statement, Morton R. Gibbons, Chairman of Council.

9:10-9:20—President's Statement, Edward M. Pallette, President.

- 9:20-9:30—President-Elect's Statement, Howard Morrow, President-Elect.
 9:30-10:00—Legislation, Junius B. Harris, Chairman of Legislative Committee.
 10:00-10:30—Hospital and Health Insurance, T. Henshaw Kelly, Chairman of Special Council Committee.
 10:30-11:00—National and State Medical Economic Problems, R. G. Leland, Director American Medical Association Bureau of Medical Economics.
 11:00-12:00—Questions and Answers on above three subjects.
 12:00-1:30 p.m.—Luncheon (Guests of the Council).

AFTERNOON

- 1:30-1:50—Postgraduate Programs, Clarence G. Toland, Chairman of Committee on Postgraduate Work.
 Discussion by Deans of California Medical Colleges.
 1:50-2:10—Public Health Institutes, C. A. Dukes, Chairman of Committee on Public Relations.
 2:10-2:30—Disciplinary Procedure, W. W. Roblee, Speaker of House of Delegates.
 2:30-2:50—County Society Programs, A. E. Varden, San Bernardino.
 2:50-3:10—Malpractice Suits, Hartley F. Peart, Legal Counsel.
 3:10-4:00—Round Table—Questions and Answers.
 4:30—Adjournment.

Secretaries will please send in any particular questions they desire to have answered.

County presidents are invited to be present and are very welcome. The Council regrets that funds are only available to pay the railroad Pullman expenses of secretaries. Should the county secretary be prevented, for good reasons, from attending, the county society is requested to send an accredited alternate, whose expenses will be paid.

Secretaries should make every effort to attend.

MORTON R. GIBBONS, *Chairman.*
 F. C. WARNSHUIS, *Secretary.*

The mutual interchange of experiences, enlightenment as to Association activities, and the presentation of immediate problems, serve to produce better understanding and unity of action. County officers attending these conferences are able to transmit to their local members a truer insight of organizational objectives and endeavors. The ultimate benefit accrues to individual members.

YOUR ADVERTISERS

With the beginning of a new year it is desirable to direct our members' attention to our advertisers. These representative business firms deal with our members and seek to serve them. They advertise in order that our members may know of the type of service they are prepared to render. They seek your business and are desirous of supplying your needs. They approach you through your JOURNAL and pay for that approach. They are your patrons and make your JOURNAL possible by lowering publication costs and thereby lower Association expenses.

For these reasons every member should give first consideration to our advertisers and when in need of supplies to place your orders with these patrons. Give preference to the detail man whose firm is one of our advertisers. Tell the detail man of a non-advertising firm that you have an obligation to patronize your advertisers. In brief, transact business with those who do business with you—your advertisers.

The Council will appreciate your adopting this policy during the coming year. Thanks.

COPYRIGHT PROTECTION

Each issue of CALIFORNIA AND WESTERN MEDICINE is copyrighted. Under the federal copyright laws, the Council holds all title and rights to every item or article contained in each issue. Under the copyright law the Council prohibits and forbids the republication of any article or item in whole, in part, or in abstract form, without first obtaining consent and permission to reprint or abstract. The Council gives this notice that violations of these restrictions will be prosecuted.

State medical journals and the *Journal of the American Medical Association* are granted permission to reprint articles and items appearing in each issue.

DUES

The beginning of a new year brings with it the necessity of paying local and state dues for the current year. Lessen the labors of your county secretary by remitting your dues promptly and relieve him of becoming a dunning collecting agent. Send in your check to your county secretary or be prepared to pay him when you go to the next scheduled meeting of your society. Your county secretary will appreciate such consideration from you.

EMPTY SADDLES

Empty saddles in the medical corral—where do we ride tonight?

On entering a new year, vital problems confront us: a state legislature about to convene, expanding federal programs for social security providing medical care, demands for open county hospitals, economists advancing plans for medical care, large employed groups demanding medical and hospital care under some prepayment plan, changing social and business conditions—all these provide reasons for us to pause and find a suitable answer to the figurative question, "Where do we ride tonight?"

The empty saddles of yesteryear's leaders must be filled with competent, capable successors for the tomorrow's rides in order that medicine and its disciples may continue in their quests of research, discovery, and distribution of medical services unmolested or hampered by outside lay or legislative domination. These movements have been under way, gaining momentum for some twenty-five years. They now constitute powerful forces, prone to ignore advice and guidance from qualified representative medical men. For many years physicians, intent upon their professional labors, chose to ignore or give scant attention to the warnings that have been repeatedly uttered. In a more or less desultory manner we stood by while these outside forces advanced on national and state fronts. Reliance was placed in our past records of professional services to fellow men, and consolation was found in our traditions, only to suddenly awaken to the fact that traditions, like treaties, are ruthlessly trod asunder. Advice to organize, to strengthen unity, to cease "resolving" and assume leadership was ignored. Minutes of many meetings contain records of warnings and pleadings, and find these pleadings relegated to files or silenced by negative action. Suddenly we find ourselves at the crossroad that we were eventually bound to come to and there we stand, wondering as to the course to pursue. The chorus swells: "Where—which way do we ride tonight?" The call is for an immediate answer born of the moment, whereas the answer should have been in process of formation these past score of years. We should have been fully prepared to present our answer of solution. As it is, our answer and policy must be formed under the pressure of the emergency. That comprises the immediate pending problem of medicine.

The answer, workable at least and subject to amendments indicated by experience gained as we progress, can be formulated, provided our members exhibit a willingness to act in a spirit of unity. Provided independent members of minority groups will yield to and support the decisions of the majority. There must be no diverging riders in the saddles of medicine.

Our House of Delegates and the Council have appointed committees that are earnestly seeking sound answers and the drafting of sound policies and plans. Confidence should be placed in these saddle-men, who are unselfishly endeavoring to ride for you. They are not lone, independent riders—they are conforming to instructions formulated by the majority, and their plans are approved by the majority before being placed in operation. Trust them. Unity of action and unity of support will bring solution and safety and insure professional security.

SCIENTIFIC EXHIBITS

The Scientific Committee plans to enlarge the scientific exhibits at our annual meeting and cause them to be an outstanding educational feature. Members are requested to file application for assignment of space to the State Secretary on or before April 1, 1937. The exhibits, in so far as possible, will be assembled in groups corresponding to our scientific sections.

In preparing and demonstrating exhibits the following suggestions should be observed:

1. The exhibitor should not attempt to show everything he has collected; the most important items should be selected.

2. Originality is encouraged.

3. Plan space between charts and place them in a horizontal position.

4. Everything should be labeled plainly.

5. Personal demonstration is advised.

In making application for space, submit a seventy-five-word synopsis, explaining the nature and purpose of the exhibit. Indicate the amount of space desired. Applications will be passed on by the Scientific Committee, and applicants will be advised as to acceptance.

DEL MONTE MEETING

It is not too early to remind members that our annual session is to be held in Del Monte the week of May 2. Hotel reservations are coming in in goodly numbers. For hotel accommodations, please refer to page 181, August, 1936, issue.

Please be reminded that *all reservations* for accommodations in hotels in the Monterey area are to be made through Mr. Carl Stanley, Hotel Del Monte, Del Monte. Mr. Stanley is in sole charge of reservations. Write him today stating the accommodations you desire. Do not delay and be disappointed. Write today.

MEETINGS

What meetings shall I attend during 1937? Members will do well to give some thought to this question and plan their work accordingly. The following suggestions are advanced:

1. *My county society.* Why? Because it is your guild. It affords you inestimable opportunities to listen to instructive papers and demonstrations and participate in their discussion. It provides you with an opportunity to be active in committee work calculated to improve professional relations, acquire public good-will, and solve questions that are related to public and professional welfare. It affords regular occasions to make professional contacts, enlarge acquaintanceships, bring about better understanding and cement professional friendships. It enables you to escape being a lone wolf.

2. *Clinics and postgraduate conferences.* Why? In order that you may remain abreast of scientific progress and be capable of rendering the highest type of medical care to your patients. They enable you to remain a "waser" in place of a "hasbeener." They keep you out of professional ruts.

3. *State meeting at Del Monte, May 2-6.* Why? For all the reasons mentioned in 1 and 2. Further, to broaden your viewpoints, to hear and see capable speakers and gain inspiration from them. To visit the scientific and commercial exhibits that are distinctly educational. To learn about state movements and pending questions. To fraternize with your friends and classmates.

4. *American Medical Association in Atlantic City the week of June 7.* Why? For all the reasons aforementioned multiplied upon a national scale. To be a better doctor and public-spirited practitioner and citizen.

Then consider a vacation of at least six weeks. Why? Because everyone needs a change from the routine. Needs to get away to new scenes and environment where he can pursue his own quests, relieved from all professional demands. Vacations enable one to escape those "coronary blocs" and remain hale and hearty at sixty. Plan a vacation, by all means.

If the state of finances permit, now consideration can be given to attending special meetings, clinics, and the taking of a "refresher course" in any of the branches of medicine.

Observing these suggestions will make you a better doctor and bring dividends of contentment and well-being.

"QUIT KICKING SECRETARIES AROUND"

Recently I attended the annual meeting of one of our county societies. The secretary, in making his annual report, stated that he had endeavored to give as much time as possible to his office and sought to serve in his best

capacity. However, he stated, "I do not like to be blamed for everything the Society does or does not do and be accused and made the Society's 'goat.' Possibly there is something wrong with me or the Society."

Such are the rewards of an efficient, zealous county secretary, and such is all too frequently the appreciation for contributed time and effort. There should be a cessation of such lack of appreciation of the services of county secretaries. "Quit kicking them around."

However, a prominent member arose and said, "The trouble with this society is its sixty-five members. Many doctors find that it is less effort to sit on the tuberosities of their ischii than stand on their feet and easier to use their mouths than to think."

Moral: There is need for more effort and unity. More thinking before talking.

OPTIONAL DEFENSE

Upon the payment of \$10 per year, members of this Association can obtain optional legal services from the medical society of the State of California, provided that they carry indemnity insurance with some approved company. Application membership blanks may be obtained from the State Secretary.

This society provides its members with the legal services of an attorney in the event they are threatened or sued for alleged malpractice. That attorney becomes the member's *personal* attorney. He will protect your personal interest, supervise your defense procedures, protect your rights, and join with your insurance company's attorney so as to assure that the provisions of your policy are fully carried out for your protection. Your interests are in his hands and he will assume full direction in all actions, thereby relieving you of these details and worries.

This *personal* legal service is worth many times the amount you pay in annual membership dues in this society. In these days when one out of every twenty doctors will probably become a defendant in a malpractice suit, no practicing physician can afford to be without this personal legal service from a staff of legal experts in medical jurisprudence. Write for membership application.

EXECUTIVE COMMITTEE (Abstract of Minutes)

The December meeting of the Executive Committee was held in San Francisco, December 12. All members were present.

Legislative matters were discussed with the Legislative Committee. Proposed legislation related to hospitals, and medical service insurance was considered and recommendations formulated.

The program for the secretaries' annual conference on February 6 was approved.

The annual budget was reviewed and referred to the Council.

A report from the Committee of Five was reviewed and recommendations were made to the committee.

Social Security program was discussed and committees were appointed.

Dr. Harvey G. McNeil of Los Angeles was appointed secretary of the Section on Industrial Medicine and Surgery to succeed Dr. Mott Arnold, deceased.

Other routine matters were considered and indicated action taken. The session lasted from 9 a. m. to 5 p. m.

F. C. WARSHUIS, *Secretary.*

It is said that among the two billion persons who inhabited this planet during the course of the nineteenth century, not more than one person in a thousand set the slightest imprint upon it. The other 999 left the world just as they found it, without having added one jot or tittle to its stock of knowledge and without having contributed a single idea that was worthy to live. The torch of progress has always been borne aloft by the very few, by those all-too-rare pursuers of the truth whose industry kindles the spark of genius into flame.

The whole fabric of human civilization rests upon the preservation of human life and the increase of human efficiency.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

Children's Bureau Welfare Program

During the November conference in Chicago, Miss Katherine F. Lenroot, Chief of the Children's Bureau, Department of Labor, outlined the Bureau's plans regarding maternal welfare and children's medical care. Miss Lenroot stated that the work would be carried on through existing state and local agencies. Not having the opportunity to request a statement as to who constituted "existing agencies" and desiring to learn if perchance "existing agencies" might include lay social organizations, a communication was addressed to Miss Lenroot requesting this information. The urgent suggestion was made that the Bureau recognize the state and county medical organizations as the existing agencies. For our members' information we present the reply to our letter.

UNITED STATES DEPARTMENT OF LABOR
CHILDREN'S BUREAU
WASHINGTON

November 30, 1936.

My dear Doctor Warnshuis:

I appreciate your letter of the 24th with reference to my Chicago address. It was a privilege to have the opportunity of meeting with the group.

As stated in the address, the Children's Bureau welcomes most heartily the coöperation of the state medical societies in the development of the programs for maternal and child health and crippled children. However, the law specifies that we must deal with official state agencies of health. I am enclosing herewith copy of the Act and a copy of our first bulletin explaining its provisions. Coöperation with medical societies, therefore, must be developed through the official state health agencies and we can recognize only such official state health agencies as units to receive funds and be directly responsible for administration. All the funds for local administration go through the state agency. Coöperation of state medical societies has been effected through their representation on state advisory committees and through special services of committees of the state societies. The coöperation of county medical societies is enlisted through the state and local agencies in many aspects of the program.

I note the facilities that would be afforded by the maternal and child welfare standing committees and the sections on pediatrics and orthopedics. I am sure the State Department of Health will welcome such coöperation.

I trust also you will feel free to write me at any time regarding problems which come up and ways in which the coöperative federal-state program may be developed more effectively.

Sincerely yours,

(Signed) KATHERINE F. LENROOT, *Chief.*

Syphilis

To Surgeon-General Parran must go the credit for "blowing off the lid" of American prudery in regard to syphilis. The press, too, has come into the clear and now permits its linotype operators to use the term "syphilis" in place of "social disease." Public ignorance can now be combated, and public as well as professional apathy can be changed to an attitude of combative effort that will gradually reduce the incidence and complications of syphilitic infections.

"The diagnosis and management of syphilis has been written and talked about so much in recent years that there is bound to be trouble ahead for the physician who makes mistakes in diagnoses or who fails to treat the patient properly. Suits for malpractice will follow as rapidly as the public becomes acquainted with what it has a right to expect from the physician."

Professional apathy of physicians in regard to syphilis arises from their lack of fundamental training. For the

physician in practice this lack of fundamental training must be compensated by our county and state societies, editors of medical journals, postgraduate conferences and medical clinics in the providing of competent facilities whereby the practitioner may speedily acquire adequate knowledge. That is an obligation that cannot be ignored. An adequate level of professional competency must be established.

The responsibility of the physician consists of extending himself to attain this level of competency. He dare not neglect doing so because he will pay dearly for his incompetency. The public is becoming informed. This department is receiving an increasing number of inquiries from lay persons seeking information as to where they may obtain dependable information and literature on syphilis. The layman will soon learn whether his physician has been competent in caring for his infection. Our concern is: Will the physician be competent?

The Committee on Public Relations is giving consideration to this subject and hopes at an early date to submit some specific recommendations.

Radio Broadcasts

The American Medical Association is presenting a series of dramatized broadcasts under the title of "Your Health." These valuable educational dramatizations are broadcast over the Blue and Pacific network of the NBC. The program and time is announced in each issue of the *Journal of the American Medical Association*.

If your local station is not broadcasting this program, it is suggested that county medical societies, through designated representatives, interview your station manager and urge that "Your Health" be included in the local programs. This action will be most helpful in bringing dependable information to your community. Tell your patients and friends to listen in at the designated day and hour.

COMPONENT COUNTY MEDICAL SOCIETIES

HUMBOLDT COUNTY

The Humboldt County Medical Society met on the evening of December 3 at the General Hospital, with President J. S. Woolford presiding. Eighteen members were in attendance. The question of hospital insurance and city tax against the physician was widely discussed.

The following officers were elected for 1937: Allan R. Watson, president; Francis Stump, vice-president; Lawrence A. Wing, secretary; John A. Lane, treasurer. Delegate to California Medical Association, G. F. Norman; alternate, J. S. Woolford.

LAWRENCE A. WING, *Secretary.*

✽

LASSEN-PLUMAS-MODOC COUNTY

A meeting of the Lassen-Plumas-Modoc Medical Society was held in Susanville Friday, November 13, following a banquet at the Grand Café.

Guest speakers were Dr. Phillip Pierson and Mr. Higbee of the California Tuberculosis Association. A plan for the examination of the school children by tuberculosis test and x-ray was outlined and the medical society expressed its approval of such a plan, although it was obvious that many difficulties would be encountered.

Guests included Doctor Cartwright of the United States Indian Service at Fort Bidwell and Doctor Kunkel of the Secret Valley C. C. C. Camp.

FRED J. DAVIS, JR., *Secretary.*

✽

MARIN COUNTY

At the recent monthly meeting of the Marin County Medical Society, held at the Marin Golf and Country Club, election of officers for the following year was held. The newly elected officers are: Anne C. Brady, president; Scott W. Pollard, vice-president; and Carl W. Clark, secretary-treasurer.

CARL W. CLARK, *Secretary.*

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

PLACER COUNTY

The Placer County Medical Society held its annual meeting in Auburn on Saturday evening, November 7.

The following officers were elected: C. E. Lewis of Auburn, president; William A. Miller of Auburn, vice-president; and Robert A. Peers of Colfax, secretary-treasurer.

Delegate L. W. Empey of Roseville and Alternate Mildred E. Thoren of Weimar were elected last year for a period of two years. Therefore there is no change in delegate and alternate.

ROBERT A. PEERS, *Secretary*.

SAN BERNARDINO COUNTY

The San Bernardino County Medical Society met at the San Bernardino County Charity Hospital on Tuesday, November 10, at 8:15 p. m.

The application for membership of Dr. Kenneth H. Abbott was favorably voted upon. Dr. H. A. Hall's application for transfer from the Los Angeles County Medical Society was voted on and approved.

Dr. F. F. Abbott, chairman of the Committee on Public Relations, reported on the Pioneer Insurance Company. The Pioneer Insurance Company (reorganized G. M. A.) has passed the State Commissioner and is permitted to write life and medical insurance. The medical insurance policy examined by Doctor Abbott is limited in its scope, although the advertising circular states that the policy "pays your hospital and doctor bills."

It was moved by Doctor Clough and seconded by Dr. X. Olsen, that Chapter I, Section 4-e, of the Constitution (regarding the expulsion of a member) be changed to the procedure advised by the California Medical Association, which has been printed in the official bulletin for the past two consecutive months. Passed.

Doctor Mock announced the meeting with the Riverside County Society on January 6, 1937.

The program of the evening was then given as follows:

Case Report—Diagnostic Problem in Splenic Anemia, Dr. Charles A. Wylie and Dr. Arthur E. Varden. Dr. C. C. Owen discussed differential diagnosis of Cooley's anemia and Gaucher's disease from the x-ray pictures.

Mr. Charles A. Son of the Industrial Accident Commission discussed the following points:

1. Compensation. Necessary form should answer the following points: (a) What is the patient's trouble? (b) Did the injury occur while employed?

2. Mr. Son requested a list of men in their respective specialties from which the Commission may select a consultant, etc., in certain cases.

Epileptiform Convulsions: The Newer Methods of Diagnosis and Treatment, Dr. Mark A. Glaser, of Los Angeles.

A. E. VARDEN, *Secretary*.

SAN JOAQUIN COUNTY

The regular meeting of the San Joaquin County Medical Society was held November 5 in the Medico-Dental clubrooms, in Stockton. The meeting was called to order at 8:15 p. m., President T. C. O'Connor presiding.

The regular meeting was preceded by the customary supper meeting at the Hotel Wolf at 6:30 o'clock, Vice-President John Blinn presiding. Eighteen members were present. Dr. H. S. Chapman spoke on *Sidelights on the Pan-Pacific Surgical Meeting in Honolulu*.

The petitions of Dr. E. A. Anderson and Dr. John T. Heavy for membership in the San Joaquin County Medical Society were read and referred to the Admissions Committee.

Doctor Collis read and submitted a list of donors for blood transfusion from the College of the Pacific. The list was placed on file for future reference.

Nominations for officers for 1937 were as follows: John F. Blinn, president; A. L. Van Meter and A. C. Boehmer, first vice-president; H. W. L. Collis, second vice-president; G. H. Rohrbacher, secretary-treasurer.

Board of Directors—T. C. O'Connor, B. J. Powell, Jr., P. B. Gallegos, Dewey R. Powell, Neill P. Johnson, George H. Sanderson, C. A. Broadus, R. T. McGurk, C. V. Thompson, J. J. Sippy, and N. P. Barbour.

Delegates to State Society—Dewey R. Powell, H. E. Kaplan, J. F. Doughty, and George H. Sanderson. Alternates—M. H. Smyth, C. A. Broadus, and P. B. Gallegos.

The paper of the evening was on *Industrial Medicine and Surgery* by Dr. L. J. Newman. He dwelt on the history of the act and the changes which have come about since 1914.

He emphasized the necessity for clear and prompt reports and explained the importance of details. Compensation is paid entirely on medical evidence, but it is not the policy of the Board to switch patients from one doctor to another, except in the matter of consultation with specialists.

There being no further business the meeting was adjourned, followed by refreshments.

The annual meeting of the San Joaquin County Medical Society was held as a dinner meeting at the new Basque Hotel, 443 South San Joaquin Street, at 7 p. m. Thursday, December 3. In the absence of President Thomas C. O'Connor, Second Vice-President Van Meter presided.

By unanimous consent the reading of the minutes was omitted and the secretary-treasurer's annual report postponed to the next meeting.

The applications of Drs. E. A. Anderson and John T. Heavy, being approved by the Committee on Admissions, were read, and there being no objection from the floor they were declared elected to membership.

The following is the report of Doctor O'Donnell on the annual ballot for the election of officers for 1937: John F. Blinn, president; A. C. Boehmer, first vice-president; H. W. L. Collis, second vice-president; G. H. Rohrbacher, secretary-treasurer.

Board of Directors—T. C. O'Connor, B. J. Powell, Jr., P. B. Gallegos, G. H. Sanderson, C. A. Broadus, C. V. Thompson, and D. R. Powell.

Delegates to State Society—D. R. Powell and G. H. Sanderson.

Alternates—C. A. Broadus and P. B. Gallegos.

Dr. Alex Anderson of Fresno, counselor for our district, was the first speaker of the evening. He presented the matter of *Ethical Advertising* as being carried on in Fresno and recommended that it be more widely used. He recommended the spread of hospital insurance as a buffer for poorhouse medicine, which has never proved successful. He spent further time on the county hospital problem and the impending legislation.

Dr. F. C. Warnshuis, Secretary of the California Medical Association, was the second speaker. He said the problem of the State Association is to keep the individual practitioner abreast of the progress in medicine and to educate the public as to the privileges and advancements of modern medical practice. He spoke further of the medical legislation as it could be expected to develop in our own legislature and in the national congress.

C. A. BROADUS, *Secretary Pro Tem*.

SAN LUIS OBISPO COUNTY

The regular monthly meeting of the San Luis Obispo County Medical Society was held on November 21 in San Luis Obispo. The speaker of the evening was Dr. H. Verrill Findley of Santa Barbara, who presented a paper on the *Injection Treatment of Hernia*, and illustrated the same by means of slides and motion pictures.

The Society decided to request one of the two Council-approved hospital insurance plans, to make arrangements for issuing policies in this county.

E. D. ANDERSON, *Secretary*.

SAN MATEO COUNTY

The meeting of the San Mateo County Medical Society was held in the staff room of the Mills Memorial Hospital at 8 p. m., Doctor Holmes presiding.

The secretary read a letter from the California Medical Association concerning the legal and ethical aspects of the

corporate practice of medicine. Doctor Holmes then introduced Dr. Frederick C. Warnshuis, Secretary of the California Medical Association, who mentioned the fact that the letter had been prepared by the legal staff of the State Association, following the adoption of a resolution at the annual meeting of the House of Delegates of the California Medical Association concerning the corporate practice of medicine.

Dr. Karl Schaupp, chairman of the Executive Committee of the California Medical Association, was next introduced. In connection with the problem of the corporate practice of medicine, he referred to the development of hospital service insurance plans in the State of California and mentioned the fact that certain features of the problem were related to some of the aspects of the problem of hospital service insurance. In discussing the legal aspects of corporate medical practice, Doctor Schaupp stated that the resolution adopted in the Coronado session was not designed to encourage the involvement of every possible case of suspected or proved corporate practice of medicine in a strict analysis of the law. "In those cases where no positive harm accrues it may be advisable," said Doctor Schaupp, "for physicians to wait until they had developed something constructive to offer before attacking such procedures."

Dr. Alfred L. Phillips, councilor for the Fifth District, asked that the problem, as it affected the San Mateo County Medical Society, be more adequately stated.

Doctor Holmes asked the secretary to give a résumé of the situation. It was pointed out by the secretary that certain members of the Society had requested an opinion concerning the practice of medicine by physicians appointed by certain corporations where such practice involved care for sickness and accident complaints of these employees, and in certain instances their dependents, the rate for such services to be dictated by the corporation involved. The secretary expressed the feeling that it was the opinion of some members of the Society that such practices were not in accordance with the principles of professional conduct in that they constituted unfair competition and might well tend to lower the standards of medical practice. Another matter involved in this problem was the question of physicians caring for lodge members at reduced rates. After the elucidation of the problem by the secretary, Doctor Murphy pointed out that another phase of the matter involved the fact that the patient did not have free choice of physician.

Dr. Ralph D. Howe stated that the principle adopted by one of the oil companies did not include care for dependents, and expressed the opinion that in view of the fact that the physician's fee was guaranteed, the doctor should have no objection to providing such care at the reduced schedule.

Doctor Holmes mentioned the fact that after consulting with several employees of one of the oil companies, it was his impression that the employees themselves were not particularly interested in that type of care.

Dr. Howard Mawsley emphasized the fact that free choice of physicians was essential to the practice of medicine, according to recognized standards of professional conduct.

Doctor Schaupp again took the floor and mentioned the fact that one large firm in San Francisco had proposed a similar plan, but after consultation with the San Francisco County Medical Society, decided to cooperate with the doctors and dropped the matter. He stated that competition under such plans is very definitely present and constitutes a very bad feature of such practice. He felt, however, that before any organized group of physicians take action either against a given corporation or against physicians aiding and abetting corporations to follow such plans, a better plan than that offered by said corporations must be advanced, because as long as there is a demand for such service a minority of physicians will be willing to supply them. Doctor Schaupp expressed the opinion that if the organizations of physicians were as closely knit as are most of the trade-unions no difficulty would arise in connection with these problems. He suggested that it might be possible for organized physicians to work out a plan in cooperation with corporations desiring to supply medical service to their employees. A general discussion ensued.

Doctor Warnshuis gave a very helpful and illuminating summary of the problem and proposals for its solution. He reaffirmed the fact that while it was definitely illegal for corporations to practice medicine except where the statute specifically provides for such practice as in the case of the Industrial Accident Commission, owing to many and varied factors, it is impossible to get a district attorney to prosecute corporations involved; and by the same token, where a physician aids and abets a corporation to practice medicine he is breaking that section of the law coming under the Medical Practice Act, and in this instance the Board of Medical Examiners has not seen fit to prosecute the physician in question. Furthermore, there is no denying the fact that from the standpoint of medical ethics such practice constitutes unprofessional conduct. "However, in spite of these principles," stated Doctor Warnshuis, "the answer to the problem is not yet available." Doctor Warnshuis mentioned the fact that the Council of the California Medical Association has proposed to prepare a bill involving the formation of a corporation whose function it will be to present a program whereby in cooperation with certain corporations desiring such services a plan will be inaugurated providing medical service for employees of such corporations. Speaking as the official representative of the State Association, Doctor Warnshuis counseled the county society not to attempt anything radical in regard to the enforcement of the general principles outlined above, but to mark time for a while; at the same time, however, to discourage members of the Society from entering into agreements with corporations which propose to practice medicine. He further stated that the State Association definitely condemned the practice of supplying care for dependents of employees at industrial rates. His final word was that whatever plan might be adopted, its success would depend upon the fact that its operation was in the hands of the physicians.

The secretary then made a motion that the chairman appoint the legislative committee to study this problem and present a resolution embodying the principles outlined by the representatives of the State Association, and to supply an answer to the question concerning the attitude of the San Mateo County Medical Society toward its members who propose joining the medical staff of corporations who desire to secure medical care for their employees at industrial rates. This motion was seconded and carried unanimously.

Doctor Holmes announced that the San Mateo Tuberculosis and Health Association, in connection with its Christmas Seals sale drive, was presenting a radio program over radio station KGO Tuesday evening at eight o'clock, wherein Doctor Murphy was to be interviewed concerning the preventive work anticipated by the San Mateo County Tuberculosis and Health Association and by the San Mateo County Medical Society.

The chairman announced the names of the officers nominated by the Board of Directors for the ensuing year: Doctor Howe, president; Doctor Ray, vice-president; Doctor Bridgman, secretary. Dr. N. D. Morrison was nominated for membership on the Board of Directors. Doctor Holmes called for nominations from the floor, and Dr. H. Hill nominated Doctor Gregory of Redwood City for the presidency. The nomination was seconded by Dr. Jewel Booth Murphy.

J. GARWOOD BRIDGMAN, *Secretary*.

SISKIYOU COUNTY

The last meeting of the Siskiyou County Medical Society for 1936 was held on December 13. The meeting was called to order by the president, Dr. C. C. Dickinson.

A representative of the Intercoast Hospital Insurance Company was to have been present to discuss plans of hospital insurance, but as he was unable to be here this matter was postponed until the next meeting.

Dr. C. C. Dickinson, who is a member of the high school Board of Trustees, stated that the matter of tuberculin testing of all high school children in Siskiyou County had been taken up with the Board and they had approved the idea. The California State Tuberculosis Association is to be notified to that effect. Dr. Albert

Newton of Yreka presented an interesting case of intussusception in an eight-months-old baby boy.

The following officers were elected for 1937: E. F. Carlson of Fort Jones, president; J. T. Steele of Duns-muir, vice-president; J. B. Maguire of Mt. Shasta City, secretary-treasurer; C. C. Dickinson of McCloud, dele-gate; V. W. Hart of Yreka, alternate.

The next meeting of the Society will be held in Yreka on February 14, 1937.

E. F. CARLSON, *Secretary*.

✱

TULARE COUNTY

The Tulare County Medical Society met in regular meeting at Motley's Café in Visalia on November 15. Dinner preceded the educational program.

Dr. Ottiwell W. Jones, Jr., of the University of Cali-fornia neurosurgical staff, presented a paper on *Head In-juries and Method of Treatment*. Lantern slides were used to clarify and illustrate his talk.

Following the paper a general discussion of neuro-surgical problems were ably answered. The paper was thoroughly appreciated by those in attendance.

Doctor Zumwalt suggested a nominating committee for the coming election of officers, but this was not acted on.

KARL F. WEISS, *Secretary*.

✱

VENTURA COUNTY

The regular monthly meeting of the Ventura County Medical Society was held at the Ventura County Country Club on Tuesday, October 13, at 7 p. m.

Following the dinner the meeting was called to order by Doctor Shore. Communications from the State Secre-tary's office were read. A short report of the Coronado session was given by the secretary.

Doctor Coffey, Program Chairman, then opened a dis-cussion on the *Feasibility of the San Fernando Plan for Ventura County*. After several minutes of fruitless dis-cussion, it was decided to postpone the matter. None of the proponents of the plan were present.

Doctor Coffey introduced Doctor Homer of Ventura, who presented an interesting paper on *Gall-Bladder Dis-eases*. Doctor Shore opened the discussion.

A. A. MORRISON, *Secretary*.

CHANGES IN MEMBERSHIP

New Members (15)

Alameda County.—Floyd I. Hohnstein.

San Diego County.—Ruth H. Hubbert, Arthur A. Mar-low, John B. Minna, Arthur D. Tuttle.

San Francisco County.—Elmer C. Bricca, E. Francis Egleston, Philip K. Gilman, Jr., John J. Hopkins, Sophie M. Loven, Joseph S. McGuinness, J. Maurice Robinson, Jerome F. Zobel.

Yolo-Colusa-Glenn County.—Edwin K. Copeland, John B. Hollingsworth.

Transferred (8)

Fred J. Crease, from Los Angeles County to Kern County.

Clarendon A. Foster, from Los Angeles County to Monterey County.

Horace A. Hall, from Los Angeles County to San Ber-nardino County.

H. M. Hawkins, from Los Angeles County to Kern County.

Lester Jankay, from Los Angeles County to Santa Bar-bara County.

Roderick A. Ogden, from Los Angeles County to San Francisco County.

William H. Wimp, from Los Angeles County to Orange County.

J. Guild Wood, from Los Angeles County to Oklahoma.

Resigned (1)

H. Ross Magee, from Los Angeles County.

In Memoriam

Arnold, Mott Hunton. Died at San Diego, December 9, 1936, age 53. Graduate of the University of Illinois College of Medicine, Chicago, 1907. Licensed in Cali-fornia in 1915. Doctor Arnold was a member of the San Diego County Medical Society, the California Medical Association, and the American Medical Association.

✱

Ball, Jau Don. Died at San Francisco, November 25, 1936, age 56. Graduate of the University of Virginia De-partment of Medicine, Charlottesville, 1902, and licensed in California the same year. Doctor Ball was a member of the San Francisco County Medical Society, the Cali-fornia Medical Association, and a Fellow of the American Medical Association.

✱

Bigby, Margaret Helen. Died at Whittier, September 26, 1936, age 49. Graduate of the University of Michigan Medical School, Ann Arbor, 1917. Licensed in California in 1919. Doctor Bigby was a member of the Los Ange-les County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

✱

Hemken, Louisa. Died at Los Angeles, November 20, 1936, age 32. Graduate of Rush Medical College of the University of Chicago, 1929. Licensed in California in 1930. Doctor Hemken was a member of the Los Ange-les County Medical Association, the California Medical Association, and a Fellow of the American Medical As-sociation.

✱

Hieronimus, Arthur. Died at Alameda, December 5, 1936, age 65. Graduate of Bellevue Hospital Medical Col-lege, New York, 1897. Licensed in California in 1902. Doctor Hieronimus was a member of the Alameda County Medical Association, the California Medical As-sociation, and a Fellow of the American Medical As-sociation.

✱

Kendall, Oscar J. Died at San Diego, November 18, 1936, age 77. Graduate of Tulane University of Louisiana School of Medicine, New Orleans, 1884. Licensed in Cali-fornia in 1899. Doctor Kendall was a member of the San Diego County Medical Society, the California Medi-cal Association, and a Fellow of the American Medical Association.

✱

Lund, Charles Walter. Died at Willows, November 4, 1936, age 60. Graduate of the College of Physicians and Surgeons, San Francisco, 1903, and licensed in Cali-fornia the same year. Doctor Lund was a member of the Yolo-Colusa-Glenn County Medical Society, the Cali-fornia Medical Association, and the American Medical Association.

✱

Witherbee, Orville O. Died at Los Angeles, De-cember 24, 1936, age 70. Graduate of the Northwestern University Medical School, Chicago, Illinois, 1893, and licensed in California the same year. Doctor Witherbee was a member of the Los Angeles County Medical As-sociation, the California Medical Association, and a Fellow of the American Medical Association.

✱

Woods, Donald Kendrick. Died at San Diego, De-cember 10, 1936, age 46. Graduate of Rush Medical Col-lege, University of Chicago, 1913. Licensed in California in 1924. Doctor Woods was a member of the San Diego County Medical Society, the California Medical Associ-ation, and a Fellow of the American Medical Association.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

News Letter

December 12, 1936.

Dear Auxiliary Members:

There are several things to be brought to your attention, and I think the new year is a good time to do this:

The Doane Trophy. This trophy was donated by Mrs. Philip Schuyler Doane to be given to the Auxiliary obtaining the largest number of new members during the year. This does not necessarily mean that only the large auxiliaries can compete for the trophy; if the small auxiliaries can get their membership up to or approximating 100 per cent, they will be considered when the award is to be made. It is up to every member to do her part to induce all who are eligible to join and help her auxiliary win the coveted trophy.

The National News Letter. This is issued four times a year by the National Auxiliary. To quote Mrs. Fitzgerald, our president: "The object of the News Letter is to pass from one group to another, news of interest and suggestions for new activity. This interchange of ideas and information is stimulating because from it evolves a feeling of friendliness between the different sections of the country—a feeling of friendliness which comes from the realization of our common problems. The News Letter cannot, of course, be valuable from the standpoint of literature, but it can be valuable as a distributor of news. You can contribute to its value and usefulness by sending in bits of news you think might be of interest to others." The subscription price is \$1 a year, and each county publicity chairman would benefit by reading the News Sheet.

Hygeia. Have you sent in your subscription to *Hygeia*? You all know what the magazine stands for and how interesting it is. Please do not forget to renew your subscription now and try to get a new subscriber as well.

The Courier. This, our semiannual newspaper, has been published, and every Auxiliary member had a copy mailed to her. If you did not receive any, please notify me and I will attend to it immediately.

Very best wishes for a Happy and Prosperous New Year.

Sincerely yours,

MRS. ROBERT M. FURLONG,
Press and Publicity Chairman.

* * *

Component Auxiliaries

Alameda County

The Woman's Auxiliary to the Alameda County Medical Association, with eighty members and guests present, met on Friday, November 20, at the Claremont Country Club, Oakland.

Mrs. Thomas J. Clark, as the reception chairman, received members in the lobby of the Club for a social half-hour before convening for luncheon. The tables were festively decorated with red berries of the season.

Following the luncheon, Dr. W. E. Mitchell gave a most inspiring talk on *The Romance of Medicine*. He followed the advance of medicine from its crude beginnings down to the present day. He took us back to ancient Greece to Hippocrates, who is said to be the first man to have given modern thoughts to medicine, and to have contradicted the old belief that disease in a patient was supernatural.

Doctor Mitchell stressed the point that the downfall of ancient civilizations was moral degeneration due to the

ravages of war and disease, and brought about through the lack of medicine and surgery.

But it was not until the tenth century that the first medical school was established in Salerno. In the fifteenth century, a ban was put on the study of anatomy. But this did not stop the study of those men who were hungering for knowledge. Later the church came to their rescue, and from then on the advance of science moved steadily on.

Doctor Mitchell gave a short résumé of the lives of some of the great men who contributed so largely to the advance of medicine and surgery, such as Galen, Morton, Pasteur, and Lister. He also said in part that enough cannot be said of the great work done by the public health departments of this country. It was through their efforts and investigation that typhoid fever, yellow fever, and bubonic plague have been brought under control.

Doctor Mitchell accompanied his talk with slides illustrating his subject-matter.

In closing, he said that in spite of the great strides made in the last few years in medicine, surgery and scientific research, he felt that there were still much greater things ahead of us, and that it was especially important that interest in the scientific approach of problems be kept alive in the minds of the public of today.

A short business meeting followed, conducted by Mrs. Clarence Page, after which the meeting adjourned until January.

MRS. JOHN OHANNESON.

✽

Orange County

Beautiful Christmas music made up the program for the musicale tea to which members of the Woman's Auxiliary to the Orange County Medical Association invited guests Tuesday afternoon in the Ebell Clubhouse lounge. Forty members and visitors made up the gathering.

Dispensing with business in short order, Mrs. K. H. Sutherland, president of the group, introduced two out-of-town visitors—Mrs. B. H. Sherman, councilor of the Los Angeles district auxiliary to the California Medical Association, and Mrs. A. Downs of the Los Angeles auxiliary—and welcomed the other guests who were sharing the afternoon with the members.

The meeting was then turned over to the Program Committee, who presented three talented guest artists—a boy soprano, harpist, and vocalist.

Duncan McCleod, youngest of the artists, opened the program with three Christmas numbers—"Adeste Fidelis," "Alleluia" by Mozart, and "Ave Maria" by Schubert. He was accompanied by his mother, and in the last also by Miss Regina Wahlberg of Fullerton, harpist.

His second group, given in Scotch costume and the McCleod clan plaid, included "Lassie o' Mine," "One Hundred Pipers," and "Safest o' the Family."

Miss Wahlberg, a talented harpist, played three numbers—"My Heart at Thy Sweet Voice" from "Samson and Delilah," "Volga Boatman," and "Trees."

Mrs. E. Wagner of Santa Ana, the third artist, sang three lovely soprano numbers—"Habanera" from "Carmen" by Bizet; "There Is a Garden" by Proctor, and "Ecstasy" by Rummel. All of the numbers were delightful and the three musicians received much applause.

During the social hour following, Mrs. H. D. Newkirk of Anaheim and her committee of doctors' wives from that city served a dainty tea collation, spreading their table with a pretty cloth which Mrs. H. A. Johnston brought from Italy. Red and gold appointments and flowers were used on the table, and those assisting Mrs. Newkirk were the Mesdames Johnston, George Paige, C. A. Neighbors, K. G. Parks, John Woods, and E. H. Kersten.

This will be the last meeting of the Auxiliary until February, Mrs. Sutherland announced.

✽

Los Angeles County

Sounding the modern note of coöperation between organized groups, the Woman's Auxiliary to the Los Angeles County Medical Association has perfected a plan to work with the health departments of the Parent Teacher Association of the city and county.

† As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

The plan was presented at the luncheon November 24 at the County Medical Building, with 110 members present and sixteen leaders of the Parent-Teacher Association as special guests.

The Auxiliary is offering two prizes to the Parent-Teacher groups doing the best health education work during the coming year. Twenty subscriptions to *Hygeia* will be given to the winning group in both the city and county districts.

After the presentation of the plan, a very stirring talk was given by Dr. Herbert Anderson on *Abundant Health*, followed by Mrs. E. B. Plimpton in a short paper on *Nobel Awards in Medicine*.

Another distinguished guest was Dr. Edward M. Pallette, president of the State Medical Association, and member of the advisory board of the State Congress of Parents and Teachers, who warmly commended the movement of the Auxiliary to work in coöperation with the Parent-Teacher Association, declaring that "The Parent-Teachers reach the public with their program, and the Woman's Auxiliary is in a position to furnish authoritative information on health questions."

MRS. ROBERT L. CARROLL.

Health Education Project

The National Education Association gives health first place among the seven objectives of education. The object of the Health Education Project of the Woman's Auxiliary to the Los Angeles County Medical Association is to help parents and children to appreciate the difference between potentially harmful health fads and basic health facts.

Believing that better health conditions will follow wider and more complete dissemination of basic health facts among parents and children, through active participation with health chairmen of local Parent-Teacher Associations in an organized better health program, the Woman's Auxiliary to the Los Angeles County Medical Association will offer prizes to the health committee judged to have made highest scores in the better health activities listed on the accompanying sheet.

Prizes will be awarded as follows:

1. Twenty one-year subscriptions to *Hygeia*, to be given to the two associations in First District Parent-Teacher Association judged by the committee to have attained the highest record of achievement in a better health program.
2. Twenty one-year subscriptions to *Hygeia*, to be given to the two associations in Tenth District Parent-Teacher Association judged by the committee to have attained the highest record of achievement in a better health program.

Study envelopes, containing articles on subjects pertaining to health, such as communicable disease control, prevention of blindness, milk, and the physically handicapped, are available free to those participating in this project. Health plays, suitable for children or adults, for the entertainment feature of a health program are also available. A Speakers' Bureau, offering speakers on a wide variety of health subjects, will provide speakers for your programs if you will call at least two weeks in advance.

Rules of Contest

1. Application blank signifying intention of local Parent-Teacher Association participation, must be filed with the Woman's Auxiliary to the Los Angeles County Medical Association by February 1, 1937.
2. Report of activities on blank provided must be filed in the Auxiliary office by May 1, 1937.
3. Submitted contest data will be judged by a Committee on Awards, composed of two members from the Auxiliary, one from First District Parent-Teacher Association, one from Tenth District Parent-Teacher Association, and one from the School Health Department.

✽

Marin County

The Woman's Auxiliary to the Marin County Medical Society held its regular monthly dinner meeting at the Marin Golf and Country Club, San Rafael, on Thursday evening, November 19, 1936.

Mrs. T. Gocher, chairman of *Hygeia*, opened her *Hygeia* drive by asking each member to obtain at least two subscriptions before our next meeting in January.

Copies of the constitution of the Marin County Auxiliary were distributed among the members present. It was decided that our auxiliary should subscribe to the National News Letter for our president.

Plans for a bridge party to be given the latter part of January, to augment the fund in our treasury, were left in the hands of the Entertainment Committee.

Following the dinner and business meeting, Dr. Bernard Kaufman of San Francisco gave a most interesting talk, illustrated by motion pictures, on *The Relation of Palestine to the Mediterranean Problem*. It was a comprehensive account of the political situation in the Mediterranean, with particular reference to the Palestine section, its natural resources, and the amazing growth of the reforested area surrounding the city, as well as the remarkable growth of Palestine.

BERDELLA M. ROBERTSON, *Publicity Chairman*.

✽

Sacramento County

The Woman's Auxiliary to the Sacramento Society for Medical Improvement met in Sacramento on November 17, 1936, at which time the reports of the various activities of the Society were read.

The tuberculosis test in the Main High School reported 28 per cent were positive. The work was very interesting, and the ladies who assisted were: Mesdames York, Cook, Norris Jones, Scatena, Sontar, Hipp, Pitts, Millar, and Brown. Motion pictures were taken of the whole procedure. Other members have been busy folding tuberculosis seals, folding envelopes, under the direction of Mesdames Walter Hicks, Vaniva, Krull, George Spencer, Sontar, Kammer, and H. J. Davis. The Red Cross drive was under the direction of Mrs. Orrin Cook.

Mr. Leo Baisden, assistant superintendent of schools, spoke on *The Rehabilitation of the Crippled Children of Sacramento*. Mrs. Donald Benson, accompanied by Miss Isobel Taylor, was the guest soloist. Hostesses were Mesdames George Spencer, Paul Grittman, J. D. Coyle, G. E. Millar, George Walsh, H. H. Beauchamp, H. J. Davis, and Louis Jones.

The Sacramento Woman's Auxiliary will aid in giving the tuberculosis test to parochial schools December 14 to 16. The Christmas meeting will be held in the home of the junior past president, Mrs. Scatena, where the festivities will be full of Christmas spirit, exchange of gifts, bridge with prizes, Christmas music and carols.

Plans are being formulated for a dinner dance late in January. Mrs. Solomon N. Weil, state president-elect, will be the honored guest.

MRS. JOHN D. LAWSON, *Secretary*.

✽

Santa Barbara County

In November the Woman's Auxiliary to the Santa Barbara County Medical Society held a membership tea at the home of Dr. and Mrs. Henry J. Ullmann. Doctor Ullmann is one of the district councilors of the California Medical Association, and Mrs. Ullmann graciously sent out invitations to the wives, mothers, and adult daughters of all the doctors in the county. Mrs. William R. Hunt, president, Mrs. Frank Hombach, Membership Chairman, and Mrs. Horace Coshaw, Hospitality Chairman, assisted with the arrangements. The past presidents, wearing corsages of pink sweet peas, were in the receiving line. Delightful music was furnished by a string trio. About sixty ladies enjoyed Mrs. Ullmann's gracious hospitality and the beauty of her hilltop home. Mrs. Hombach expects to add ten or twelve new names to the membership list as a result of the tea.

The December meeting of the Santa Barbara group was in compliment to Mrs. Andrew J. Thornton. On the second of the month she made a special trip from her home in San Diego to visit Santa Barbara, and was entertained at breakfast at El Encanto Hotel. Afterward she spoke to us informally of her visits to other county society auxiliaries, and our members plied her with questions until the hour grew late. After a short ride around the city, Mrs. Thornton and several of the members of the Auxiliary attended the luncheon meeting of the Health Section of the County Council of Social Agencies. Mrs. Thornton returned to San Diego that afternoon by airplane, but her inspiration and helpful suggestions remain to help us with our work.

ELISABETTA HENDERSON, *Reporter*.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11, 1937. Olin West, M. D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 3-6, 1937. F. C. Warnhuis, M. D., 450 Sutter Street, San Francisco, secretary.

Western Section: American Laryngological, Rhinological, and Otolological Society, San Diego, January 30-31, 1937. Dr. David R. Higbee, 3245 Fourth Avenue, San Diego, chairman.

Medical Broadcasts*

American Medical Association

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts, under the title "Your Health." The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title "Your Health," was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "Medical Emergencies and How They Are Met." The new series is built around the central idea that "one hundred thousand American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Blue network instead of the Red, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the health magazine, and three weeks in advance in each issue of the *Journal of the American Medical Association*.

The time of the broadcast is Tuesday afternoon, two o'clock, Pacific time.

San Francisco County Medical Society

A radio broadcast program for the San Francisco County Medical Society for the month of January is as follows:

Tuesday, January 5—KYA, 6 p. m.
Tuesday, January 12—KYA, 6 p. m.
Tuesday, January 19—KYA, 6 p. m.
Tuesday, January 26—KYA, 6 p. m.

Los Angeles County Medical Association

The radio broadcast program for the Los Angeles County Medical Association for the month of January is as follows:

Saturday, January 2—KFI, 9:15 a. m.
Saturday, January 2—KFAC, 10:15 a. m.
Tuesday, January 5—KECA, 10:30 a. m.
Saturday, January 9—KFI, 9:15 a. m.
Saturday, January 9—KFAC, 10:15 a. m.
Tuesday, January 12—KECA, 10:30 a. m.
Saturday, January 16—KFI, 9:15 a. m.
Saturday, January 16—KFAC, 10:15 a. m.
Tuesday, January 19—KECA, 10:30 a. m.
Saturday, January 23—KFI, 9:15 a. m.
Saturday, January 23—KFAC, 10:15 a. m.
Tuesday, January 26—KECA, 10:30 a. m.
Saturday, January 30—KFI, 9:15 a. m.
Saturday, January 30—KFAC, 10:15 a. m.

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Symposium on Heart Disease.—The postgraduate symposium on heart disease, given at San Francisco on November 18 and 19, the program of which was printed on page 442 of the November issue, recorded an attendance of California physicians representing some fifty cities.

The new officers of the Heart Committee elected for the year 1937 are as follows: John P. Strickler, M. D., chairman; William Dock, M. D., vice-chairman; and Elbridge J. Best, M. D., secretary.

Indo-Latin College of Surgeons.—A new organization, the Indo-Latin College of Surgeons, was founded in Mexico City November 20, 1936, during the meeting of the Second National Assembly of Surgeons of Mexico. It will be comprised of a membership from Mexico, Central and South America, and be patterned after similar organizations in this country, Canada, and England. The venerable Dr. Ulises Valdéz of Mexico City was chosen the first president.

At the present time a few of the Mexican surgeons are members of the American College, but it is quite apparent that due to the difference in language, customs, and nationalistic spirit of the Spanish-speaking countries, they should have their own organization. The percentage of Mexican physicians speaking English is certainly not greater than that of the American physicians speaking Spanish, and does not exceed five per cent.

Dr. Felix Miller of El Paso and Dr. Carl Hoag of San Francisco were the official representatives of the American College of Surgeons at the founding ceremonies.

School Absences and Disease Reporting.—School appropriations in California are based upon average annual attendance, with proper allowances for absences due to epidemics. Because of the wide variation in the methods employed in reporting epidemics, it has become necessary for the State Department of Public Health to adopt a uniform procedure. Following is the text of a letter upon this subject sent recently to all local health officers in the State by Dr. Walter M. Dickie, Director of Public Health:

To preserve the purpose of reporting those diseases designated by law and to insure accuracy in our statistical procedure, it has become necessary to make some changes in the method of submitting the records of those cases not attended by physicians.

Therefore, beginning with this school year, we shall refuse to accept any reports of cases of communicable diseases unless submitted to us in the regular way—that is, through the local health officer at the time the illness occurs and on the official cards provided for that purpose.

Our experience during recent years has been very unsatisfactory with reference to the procedure for reporting communicable diseases in school children. At the end of the school year, the school authorities have stressed the point of having all cases of the diseases epidemic during the school year reported, to enable us to certify to the State Department of Education that epidemic conditions did exist and thereby permit them to request emergency attendance consideration. In many instances to complete our records, the school principal or the superintendent sent us lists of children's names as cases.

These cases not attended by physicians must be reported by the parents, the nurse, or the school authorities either at the time of the illness, or when the child returns to school, these reports to be submitted to you as health officer and if acceptable to you they shall be forwarded to the State Department of Public Health.

Lists of names prepared by school authorities at the end of the school year will not be accepted. We ask that you convey this information to the school superintendents and principals in your territory.

Rheumatic Disease in Northern California.—A hint that the people of northern California should take extra precautions to guard their health during December, January, and February, to help prevent or overcome rheumatic diseases, is contained in a report by Dr. Amos Christie, instructor in pediatrics and medicine in the University of California Medical School. At the same time, Doctor Christie states, "we are dealing with a benign type of rheumatic infection, comparable with that of other communicable diseases in California."

The study made by Doctor Christie revealed "an unusually high hospital incidence and a low general incidence" of rheumatic fever in northern California. A study of 116 cases in San Francisco indicates that the incidence of carditis, or inflammation of the heart, in combination with other rheumatic manifestations, is correspondingly low.

The high hospital incidence of rheumatic disease in San Francisco is strikingly in contrast with the low general incidence, according to Doctor Christie. One reason advanced is that many persons migrate to California for their health and seek the hospitals of the big cities for the treatment of rheumatic ailments, but this reason is not fully borne out by the showing made by hospitals in other populous centers of the State. The low incidence of rheumatic fever among school children in San Francisco may also be attributed to the possibility that the disease becomes benign for long periods after its typical onset, although this is also a matter of considerable speculation.

But the fact remains, according to Doctor Christie, that in San Francisco "we deal with a relatively benign type of rheumatic infection, when measured in terms of cardiac damage resulting from the rheumatic infection."

Doctor Christie's report appears in the current issue of *The American Heart Journal*.

Too Much Sunshine, Bottled or Free, Declared Serious.—The absorption of California's widely advertised sunshine, either externally or internally, should be in moderation or serious results may follow. External consumption is represented by the sun bath and various other forms of irradiation in which either Old Sol himself figures, or his place is taken by a lamp or other contrivance. Internal consumption is represented by the vitamin D concentrates and preparations sold by drug stores or added to foods. This is the famous "sunshine vitamin."

The University of California Medical School and the San Francisco Department of Public Health have joined in a warning against too much sunshine, particularly in the concentrated form, because of the possibility of delayed harmful effects. The University's warning reads:

"Naturally this is not an argument for interfering with the treatment or prevention of rickets by vitamin D. But it is a plea to use some discretion in the amounts of vitamin D prescribed. Commercial enterprise is endeavoring to capitalize to the fullest in the current popular vogue for vitamin D. In addition to a sun-tan craze there are ballyhooed everywhere irradiated foodstuffs of all varieties, metabolized milks and even 'sunshine soaps.' But when on top of an unknown but probably quite adequate intake of vitamin D, especially in Sunny California, children are dosed with large amounts of vitamin D preparations by overanxious mothers, it is time for physicians to use care in prescribing the drug."

The warning of the San Francisco health department states:

"The director of public health wishes to record the fact that he disapproves of the present tendency of manufacturers to add measured quantities of vitamins to foods for commercial purposes. There is still considerable question, particularly in the instance of vitamin D, of what constitutes the proper dosage of vitamin concentrates in the various age groups. Any attempt to increase the sale of a food product, especially milk, by the addition of a substance whose value to the public health is still a controversial problem is indeed ill-advised. Even if it is granted that the actual danger in the consumption of vitamin D milk is relatively minimal, there is as yet no definite and accepted information on the limits or margins of clinical safety."

The University's statement was prepared by Dr. Chauncey D. Leake, professor of pharmacology, and the city's statement by Dr. J. C. Geiger, health officer.

Stanford Popular Medical Lectures.—The Stanford University School of Medicine, San Francisco, announces the fifty-fifth series of popular medical lectures to be given in Lane Hall on alternate Friday evenings at eight o'clock during the winter quarter, 1937. The dates, titles, and lecturers are as follows:

January 8—Syphilis and Its Control, Dr. Jacques P. Gray.

January 22—The County Hospital and the Public, Dr. Benjamin W. Black.

February 5—Recent Advances in the Treatment of Tuberculosis, Dr. William C. Voorsanger.

February 19—The Crippled Child, Dr. Frederic C. Bost.

March 5—Behind the Scenes of Pain Relievers in Dentistry, Dr. Sanford M. Moose.

March 19—The Rising Death Rate From Heart Disease, Dr. J. Marion Read.

Undulant Fever Symposium.—Following is the program of an undulant fever symposium recently held under the auspices of the Southern California Public Health Association and the Internal Section of the Los Angeles County Medical Society at the Los Angeles County Medical Association Building, Wilshire and Westlake avenues, Los Angeles:

General Discussion of the Problem—Dr. Karl F. Meyer, Director of the George Williams Hooper Foundation for Medical Research, San Francisco.

Public Health Problems—Dr. Wilton L. Halverson, Health Officer, Pasadena.

Laboratory Problems—Dr. Alvin G. Foord, Pathologist, Huntington Memorial Hospital.

Medical Problems—Dr. Philips J. Edson, Pasadena.

Dr. R. V. Stone of the Los Angeles County Health Department is president and Mr. Charles W. Arthur of the Pasadena City Health Department is secretary of the Southern California Public Health Association.

Cervix Cancer Can Be Sharply Reduced.—If it were possible to examine a large number of women at intervals through the simple procedure of an iodine stain, now perfected, the present high mortality from cancer of the cervix or neck of the womb would be greatly reduced. A nearly 100 per cent security for permanent definite healing is possible where the cancer or carcinoma of this type has been detected at the very beginning of its onset by means of the stain. Diagnosis of cancer of the cervix is now possible through the stain, long before the tissue change becomes apparent to the patient or possibly to the doctor himself.

These findings were detailed to the faculty of the University of California Medical School by Dr. Walter Schiller, noted pathologist of the Frauenklinik, Vienna, in a recent visit to the school. Doctor Schiller likewise detailed the long years of tedious laboratory and clinical study before the stain process could be determined or proved. He is credited with being the discoverer of the process.

"The genuine early cancers consist of a superficial layer, first without and then with cones penetrating deeply," he said. "Therefore all early growths have a smooth surface, the superficial layer lying quite flush with the normal surface and showing no papillary (nipple-like) growth, recesses or ulceration. This is what makes it so difficult to diagnose the first stage of cancer, because the superficial layer is not distinguished either in color or form from the normal surrounding epithelium."

Cancer of the cervix usually starts when the glycogen, a carbohydrate found in most of the actively functioning cells of the body, disappears from the superficial tissue. This change occurs suddenly and without intermediate stages; but it can be detected by the aqueous iodine test, which marks off the areas which contain no glycogen. This carbohydrate is always absent in cancer. If the cervix is washed with the iodine solution, normal epithelium will become stained dark brown within twenty or thirty seconds, while cancerous epithelium will remain white.

The optimal solution was also described by Doctor Schiller as pure iodine, one part; potassium iodide, two parts; water, 300 parts. The method can be applied without difficulty, with no discomfort to the patient, and quickly produces the desired showing.

Safety Nets on Golden Gate Bridge.—On July 13, 1936, the California Industrial Accident Commission held a hearing with the contractors on the steel-erection work for the suspension span of the Golden Gate Bridge, San Francisco. Following this hearing the Commission ordered nets installed for the protection of all workers who might fall during the steel erection, painting, paving, and electrical work.

In complying with this order the contractors, in coöperation with the Golden Gate Bridge and Highway District, constructed nets 120 feet wide and totaling over 6,400 feet long, extending from the concrete pylon on the San Francisco side to the corresponding pylon on the Marin side, and 10 feet beyond each side of the bridge work. The work of hanging the nets was done from four net travelers, thus providing 100 per cent protection to all workmen once the net travelers were erected.

To date, three lives have positively been saved because these men fell into the net, and without this protection would have fallen into the bay, 200 feet below.

This net is an innovation in safety on bridge construction, and due to its success not only as to safety, but because it has speeded up erection work, will, no doubt, establish a standard that will be used on future bridges.

Already the Industrial Commission of British Columbia has made inquiries into the practicabilities and cost of this net, and they will no doubt install such a net on the bridge across the narrows at Vancouver.

It is hoped all future bridges will require some form of safety net.

The Cancer Clinic in Medical and Dental Schools.—Grant E. Ward, M. D., in the December Bulletin of the American Society for the Control of Cancer, states:

"Since 1900 vital statistics in various large centers of population and in all registration districts throughout the United States have shown a steady rise in cancer mortality, until, at present, cancer is second only to cardiovascular diseases as the cause of death. (Some statistics place pneumonia second and cancer third.) The question naturally arises, 'Why the increase in cancer deaths and is it real or apparent?' Several facts come to the fore in the study of this question.

"In the last fifty years, advances in scientific medicine have changed the order of death dealing diseases. A half-century ago communicable diseases—plague, smallpox, diphtheria, typhoid, infant dysentery, malaria, yellow fever, tuberculosis—were the great scourges of the civilized world. One by one these epidemics have been conquered. The 'white plague,' which at one time led in the cause of death, is now far down the list. . . . Most of these infectious diseases took their toll of death from infants, children and young adults, so that the average age of our population about forty or fifty years ago was about thirty-five. As infectious diseases were controlled, the average age of man has gradually increased, until today it is fifty years or more. This means that people living through the average age of fifty will die of diseases occurring in the latter years of life. One of the chief of these is cancer. Cancer is recognized as a disease of middle and late life, although we are continually seeing cancer in the younger ages. Cardiovascular diseases, nephritis, and the like, are also diseases of later life and are now prominent in the cause of death as compared with a few decades ago, even ahead of cancer.

"According to the statistics of the New York Health Department, there is not an actual increase in the percentage of death caused by cancer in the various age groups.

"This report charts the cancer deaths for the various decades of life, including the years ten to eighty. Although many more persons live to the upper decades of life (above forty) than formerly, the percentage of deaths from cancer in the upper brackets is no larger than it was in 1900.

"Other factors bearing on the increase in cancer deaths throughout the country are more accurate vital statistics, correct diagnosis by x-rays, pathologic studies, and more exact diagnoses by operation.

"Interpret these data as one will, cancer is second in the toll of death throughout the country. This means that it is of paramount importance to teach medical and dental students the early symptoms of cancer and to make them 'cancer-conscious,' so that they will recognize all types of pre-malignant diseases during routine examinations." . . .

New Blood-Clot Factor Found in University of California Laboratory.—Discovery of an additional factor in the mechanism of blood clotting in humans and animals is reported from the division of biochemistry, University of California. The laboratories concerned are now trying to isolate this factor and to determine its chemical nature.

The possibility that when this work is cleared up it may play a part in the treatment of certain diseases in which abnormal bleeding is present, is expressed by the discoverers. Among these diseases are hemophilia, and hemorrhages arising from jaundiced or other conditions.

Notification of the discovery was published by Dr. David M. Greenberg of the division of biochemistry, and Clarence E. Larson, graduate student, formerly in the division and now in the laboratories of the Mount Zion Hospital, San Francisco.

Story of the Christmas Seal.—Einar Holbell, a postal clerk in Copenhagen, wanted to build a hospital for tuberculous children. As he sorted stacks of letters at Christmas time, his thoughts flashed back and forth between the cheer of holiday mail and the tears of children. From the postage stamps of his beloved Denmark on the front of mail, he conceived other colorful stickers on the back, each to be sold for a penny, the funds so derived to fight tuberculosis, greatest killer of all times.

Appealing to his king and queen, Holboell received royal approval, and thus, in 1904, was born the Christmas Seal, an idea so compelling that it has encircled the world, a mighty force for the prevention of needless deaths.

In 1907, Miss Emily Bissell of Delaware, who also wanted to build a hospital for tuberculous children, learned of the Danish Christmas Seals. She published and sold the first American Seals that year. Then the Tuberculosis Association adopted the plan, and today the aggregate of funds thus raised has reached \$80,000,000.

Silicosis in California.—The State Assembly Committee, authorized by the Legislature to investigate the problem of silicosis, met in the State Building, San Francisco, on Tuesday, November 10.

Commissioner Frank C. MacDonald reported to the committee concerning the law and the safety program inaugurated under his supervision for the purpose of protecting employees in California from hazardous exposure to dusts, fumes, vapors, and gases.

Mr. Daniel W. Burbank, attorney for the California Inspection Rating Bureau, testifying for and on behalf of the insurance companies in California who carry workmen's compensation insurance, made the following statement:

I represent the California Inspection Rating Bureau, composed of the carriers of workmen's compensation in the State of California. We are marking time on the silicosis matter and are very, very active on certain other aspects. We are marking time from the standpoint of suggesting legislation. We will have no suggestions to make to you—have none now and will make none at the coming legislature. We are, on the other hand, exceedingly active from the standpoint of silicosis in our Safety and Engineering and Prevention Departments. Our aims are exactly those of the Industrial Accident Commission—the insurance carriers' aims are those of the Industrial Accident Commission, and I can say all right-minded employers have exactly in mind what Mr. MacDonald stated so well was the primary purpose of workmen's compensation, which is to prevent disease and to permit workmen to be employed under healthful conditions. We have a large staff of inspectors and are constantly working to devise ways of avoiding this risk to employees. Under the scheme of rates set up, it is worth while to an employer to participate and coöperate, and I can also say that Mr. MacDonald is 100 per cent correct in so far as our experience goes in saying that the employers have coöperated. I think you, Mr. Chairman, very aptly said a moment ago that the legislation suggested last season and perhaps the controversy over rates, while it was distasteful, nevertheless served a useful purpose by the publicity and argument that went on, in waking up the employers of the State. I wish to say in addition simply this, that we applaud and approve Mr. MacDonald's premise. His opening statement was very splendid and very fair, and while the Workmen's Compensation Act gives the Industrial Accident Commission ample police power, yet it is absolutely unfair of the State to expect them to discharge those duties and to police industries, as industry

must be policed and inspected and educated and advised, as they so well do, unless they have adequate help to do it. This is fundamental, but the fact is they have not had it and the workmen of the State are suffering on account of it through no fault of the Commission, which is entirely competent to direct that aid if the Legislature will give Mr. MacDonald the program he has outlined here, and it will be the most remunerative expenditure of money, I think Mr. MacDonald will agree, that the State could possibly make. I applaud and approve his program, and I am sure that we meet on a common ground; that all employers and their insurance carriers and everyone who does the right thing in this regard will agree, and I only hope that some concerted action to bring this to the attention of the Legislature will be taken.

Heart Disease Symposium at Los Angeles.—The fifth annual symposium on heart disease by the Los Angeles Heart Association, a Chapter of the California Heart Association, will be held in the Los Angeles County Medical Association Building, 1925 Wilshire Boulevard, January 28-29, 1937. This will be the fifth annual symposium of the Los Angeles Heart Association, and it is the desire of the Association to continue these annual meetings if the attendance is satisfactory. The present officers of the Association are: Dr. Arthur M. Hoffman, president; Dr. William H. Leake; Dr. George H. Houck, secretary.

The evening session on Thursday, January 28, will be a joint meeting with the Los Angeles Clinical and Pathological Society. The evening session on Friday, January 29, will be a joint meeting with the Los Angeles County Medical Association. The guest speaker this year is Dr. William Dock, professor of pathology at Stanford University Medical School, San Francisco.

This program has been arranged principally for the benefit of members of the medical profession in general practice in Southern California. All physicians who are interested in the various aspects of heart disease are urged to join the California Heart Association. The annual dues are two dollars.

The program includes the following:

THURSDAY, JANUARY 28

Evening Meeting, Eight O'Clock

(Joint Meeting with Los Angeles Clinical and Pathological Society)

Problems in Heart Disease

Clinical; Physiological; and Pathological

A Round-Table Discussion: Led by Howard F. West, M.D., Burrell O. Raulston, M.D., Verne R. Mason, M.D., John W. Budd, M.D., and William H. Leake, M.D.

FRIDAY, JANUARY 29

Morning Session, 9:45 O'Clock

Treatment of Cardiovascular Syphilis—George H. Houck, M.D.

Cardiac Abnormalities in Diseases of the Thyroid Gland—Walter A. Bliss, M.D.

The Sedimentation Rate in Coronary Thrombosis—R. Manning Clarke, M.D.

Peripheral Embolism in Heart Disease—William H. Leake, M.D.

Chest Pain in Heart Disease—Morris H. Nathanson, M.D.
Diagnosis of Cardiac Infarction—James F. Churchill, M.D. (by invitation).

Afternoon Session, Two O'clock

Diagnosis of Rheumatic Fever—E. Richmond Ware, M.D.
Diagnosis of Cardiovascular Emergencies—Donald J. Frick, M.D.

Treatment of Cardiovascular Emergencies—Lewis T. Bullock, M.D.

Diuretics—Hilmar O. Kocfod, M.D. (by invitation).

The Value of Auscultatory Findings in Heart Disease—William Dock, M.D. (by invitation).

Evening Session, Eight O'Clock

(Joint Meeting with Los Angeles County Medical Association)

Heart Disease as a Community Problem—Arthur M. Hoffman, M.D.

The Significance of Dyspnea—William Dock, M.D. (by invitation).

♦ ♦ ♦

Exhibits of pathological specimens and of electrocardiograms will be found on the second floor during the Friday sessions.

NEWTON EVANS, M.D.

R. MANNING CLARKE, M.D.

Medical Conference Clinics in Oakland.—A medical conference for general practitioners, initiated by the Alameda County Institutions Commission, approved by the Alameda County Medical Association and arranged by the staffs of the Alameda County hospitals in cooperation with the University of California Extension Division, will be held in Oakland during the week of February 1 to 5, inclusive.

The object of this postgraduate course is to give the general practitioner an intensive week of study and demonstration, covering the various problems that he meets daily in general practice. To accomplish this the various departments of the Alameda County hospitals have combined their resources to give a complete course, extending over a wide field. The program includes lectures by the medical staff, supplemented by surgical demonstration of the same topics by the surgical department. The course is open to general practitioners, graduates of regular schools of medicine.

The program will be given by the assistance of the staff of the Alameda County hospitals, with Dr. Benjamin W. Black, director, in charge, cooperating with the Extension Division of the University of California.

About forty physicians will participate in the program of study. Among those who have definitely been scheduled for a part in the program are: Doctors Benjamin W. Black (director), Charles A. Dukes, Sumner Everingham, Edward N. Ewer, Harold Hitchcock, Robert T. Legge, Albert M. Meads, William H. Strietman, Fletcher Taylor, and H. J. Templeton.

Instruction will begin at 8 a. m. and continue through the whole day until 9:30 p. m. daily from February 1 to 5. The Thursday evening meeting will be held with the Alameda County Medical Society. On Friday evening, conference members will be the guests of the hospital staff at a banquet at the Claremont Country Club.

The fee for the conference will be \$25.

Program of Courses

The complete program of the conference follows:

Medical Department.—Peptic ulcer—various symptoms, diagnosis, and modern treatment; thyroid and parathyroid—symptoms and laboratory findings; gall-bladder diseases—the clinical tests, the x-ray examinations and interpretations; cardiovascular diseases; tuberculosis—sanatorium care and clinic treatment followed by a display of chest surgery, illustrating the recently advanced surgical procedures; arthritis; glandular disorders—illustrated by a series of individuals presenting glandular dysfunctions; nutrition; leukemias and anemias—both clinic and laboratory study; pneumonia—with suggestions for home treatment; communicable diseases—presented at the isolation department, where a great variety of contagious diseases will be found; orthopedics—a discussion and presentation of the common fractures met in practice.

Surgical Department.—The surgical department will assist in the medical program by demonstrating the various operations resulting from these diseases, such as thyroidectomy, gastric surgery, gall-bladder surgery. The surgical department will also present the treatment of extensive burns and surgical shock, industrial surgery, and the surgery of hernias.

The neurology department will give special emphasis upon the diagnosis and treatment of fractured skulls, so commonly met with today in private practice, due to highway accidents. A demonstration of the procedure and value of spinal punctures, cisternal punctures, and encephalography will be presented.

The genito-urinary department will present the subject of hematuria in trauma and disease. Also the treatment of acute venereal disease will be given.

The dermatology department will present an illustrated demonstration of skin diseases that are of interest to the general practitioner together with the modern treatment of syphilis.

The gynecology and obstetrical departments will thoroughly cover the subject of pelvic examination with differential diagnosis of pelvic conditions. The obstetrical department will cover the subject of complications of pregnancy and will also report methods of handling maternity cases, following delivery. Arrangements may be

made for attendance at the delivery of cases all during the week.

The cancer clinic will present the subject of cancer, its early diagnosis, pathology, and treatment, from the great number of illustrative cases and will be followed by a demonstration of cancer surgery.

The pathologic department will hold an interesting clinical pathology conference.

The x-ray department will demonstrate the use of radium, radiation, and x-ray.

LETTERS

Concerning the fight against syphilis.*

CALIFORNIA MEDICAL ASSOCIATION
DEPARTMENT OF PUBLIC RELATIONS

December 5, 1936.

To the Editor:—You are quite aware that since Doctor Parran has assumed the office of Surgeon-General of the United States Public Health Service one of his outstanding objectives is to educate the public in regard to syphilis and its complications. One of the plans of the United States Public Health Service, under the Social Security program, is the conducting of a campaign that would be nation-wide for the eradication and treatment of those afflicted with syphilis.

The Department of Public Relations of the California Medical Association is commencing to receive inquiries from lay individuals as to where they may obtain dependable information and literature upon the subject. The Committee on Public Relations is preparing, after consultation with competent members of the profession, a bibliography that may be sent to these inquiring individuals. As far as the education of the public is concerned, this committee feels that the public will gain their educational information through the activities of the United States Public Health Service and the Social Security Administration. We, however, feel that a very serious problem arises with regard to the members of our profession and their competency to recognize as well as treat this affliction. We feel that there has been a lack of professional training and education due to more or less apathy on the part of educators and the prudery of the public press as well as society. Now when the attempt is being made to educate the public, if physicians are not brought up to a level of competency and do not provide adequate care for those who consult them they will be laying themselves liable to suits for malpractice.

To that end the committee feels that organized medicine must make a very effective effort to enlighten and instruct the members of the profession.

In the November, 1936, issue of the *Archives of Internal Medicine* there is a very splendid review of recent literature and an excellent discussion of the entire question of syphilis, prepared by Doctors Padget and Moore of Baltimore.

Several of the members of this committee feel that it would be most helpful if CALIFORNIA AND WESTERN MEDICINE were, in two or three issues, to reproduce this summary for the benefit of our members. We also feel that in each issue in the department of Bedside Medicine there should be a sustained or consecutive series of articles written by competent men for the education of our public.

I am sending these suggestions to you as chairman of the Committee on Public Relations, and respectfully request that you initiate these suggestions in CALIFORNIA AND WESTERN MEDICINE.

The committee is willing to be of all assistance possible. If we can be helpful to you, please call on us.

Sincerely yours,

C. A. DUKES, M. D.

Concerning reporting of syphilis and gonorrhea.

TREASURY DEPARTMENT
PUBLIC HEALTH SERVICE
WASHINGTON

November 16, 1936.

To Coöperating Health Officers:

During the last few years, health officers and others interested in the control of syphilis and gonorrhea have heard much regarding the development of an efficient system of reporting these diseases. The Public Health Service has been requested to institute studies aimed at the improvement of morbidity reports for syphilis and gonorrhea. Meanwhile, it is highly desirable to continue the old system of collecting morbidity reports, which has been in use in health departments for a decade or more.

Attention is invited to the large number of health departments which fail to submit morbidity reports to the Public Health Service at the present time. When the plan of publishing morbidity reports for syphilis and gonorrhea in cities with a population of 200,000 or more was instituted about ten months ago, practically all of the cities submitted reports. Considerable correspondence has been held with health departments since that time in which attempts have been made to encourage reporting. In spite of this, the present monthly statement indicates a grave lack of interest. From a study of the statements which are presented herewith, one gains the impression that the extent to which such reports are made varies in direct proportion to the interest and initiative of the health officers in the various states and cities.

By direction of the Surgeon-General.

Respectfully,

R. A. VONDERLEHR,
Assistant Surgeon-General, Division of
Venereal Diseases.

TREASURY DEPARTMENT
PUBLIC HEALTH SERVICE

State health officers' monthly statement of venereal diseases reported. For the month of September, 1936.

This statement is issued monthly for the information of health officers in order to furnish current data as to the prevalence of the venereal diseases. The following reports were received from state health officers. The figures are preliminary and subject to correction. It is hoped that this will stimulate more complete reporting of these diseases.

	Syphilis		Gonorrhea	
	Cases Reported During Month	Monthly Case Rates Per 10,000 Population	Cases Reported During Month	Monthly Case Rates Per 10,000 Population
California	1,358	2.41	1,484	2.63
Total (all states).....	22,087	1.86	15,101	1.27

Monthly statement of venereal diseases reported in California cities with populations of 200,000 or over. For the month of September, 1936.

	Syphilis		Gonorrhea	
	Cases Reported During Month	Monthly Case Rates Per 10,000 Population	Cases Reported During Month	Monthly Case Rates Per 10,000 Population
Los Angeles	361	2.52	368	2.57

San Francisco *.....				

* No report for current month.

Concerning acknowledgment of Widney reprint.

LIBRARY OF CONGRESS
DIVISION OF ACCESSIONS
WASHINGTON

To the Editor:—By direction of the librarian, I beg to acknowledge with cordial appreciation the receipt from you of the gift mentioned below, a welcome addition to the collections of the Library of Congress.

Very truly yours,

FAUSTON DOWNIS,
Acting Chief, Division of Accessions.

A copy of: "Joseph Pomeroy Widney, . . . Founder of the Los Angeles County Medical Association and of the College of Medicine of the University of Southern California, civic worker and author; some biographical notes on a colleague, who, at the age of 95, still 'carries on.' By E. T. W."

* See editorial comment in this issue, page 3.

Concerning need of adequate inspection of foods canned in foreign countries.

CITY AND COUNTY OF SAN FRANCISCO
DEPARTMENT OF PUBLIC HEALTH

To the Editor:—At Doctor Geiger's direction, I am sending you the attached copy of an open letter to health officers. This letter has been sent to all state and territorial health officers and to the health officers of one hundred of the larger cities of the United States, and to a number of executives within the canning industry.

Doctor Geiger thought you might be interested in seeing a copy of the communication, inasmuch as it represents an attempt to secure new legislation which will permit of adequate supervision and regulation over canned products of both domestic and foreign origin.

On authority from the Director of Public Health.

Sincerely,

JACQUES P. GRAY, M. D.,
Assistant Director of Public Health.

1 1 1

CITY AND COUNTY OF SAN FRANCISCO
DEPARTMENT OF PUBLIC HEALTH

December 8, 1936.

An Open Letter to Health Officers:

From time to time, outbreaks of botulism have been traced to foreign canned products. Botulism has occurred in California in the past year in two outbreaks, involving fourteen people and causing, among these, six deaths. In one instance, the source of infection, epidemiologically, was traced to antipasto, a vegetable-fish product packed in one of the southern European countries; in the other outbreak, clams packed in an oriental country were responsible.

As a result of these two incidents, I addressed a communication to representatives of the United States Department of Agriculture, Food and Drug Administration, pointing out the desirability of adequate supervision over foreign canned products coming into this country and the justification for establishing safeguards similar to those required in this country in the packing of such products, so that the American consumer desiring canned products of foreign origin might be assured of the safety of such products since they would be packed under conditions involving techniques comparable to those followed in American canneries. In his reply, the Chief of the Division of State Cooperation, W. S. Frisbie, stated that existing legislation does not grant authority for the establishment of standards for canned products coming in from foreign countries. He also pointed out that the "present action and control of imported goods is quite as rigid and along the same lines as that exercised over domestic products"; also, that as a matter of fact "there are no provisions, under the Federal Food and Drug Act, which confer any authority upon the Food and Drug Administration to insist upon certain standards of processing for canned goods in foreign countries or in domestic commerce." In other words, it appears that the present high standards of canned products packed in the United States of America have been developed as the result of more or less self-imposed rigid requirements and standards as promulgated by the canning industry itself with the assistance of its consultants.

Under these circumstances it would seem that there is a definite need for widespread development of public opinion favorable to suitable legislation, giving broad powers and genuine authority to the United States Department of Agriculture or other suitable federal agency, permitting adequate supervision of commercially prepared canned food products whether packed in foreign or domestic canneries. The American consumer certainly deserves a safe canned product at all times and from all sources.

May I have your comment on this subject? Your assistance in developing public opinion favorable to worthwhile action in Congress, I am sure, would be helpful to your congressmen and senators.

Sincerely,

J. C. GEIGER, M. D.,
Director of Public Health.

Concerning contribution of California Medical Association to Lane Library.

December 22, 1936.

Dr. F. C. Warnshuis,
Secretary, California Medical Association,
450 Sutter Street,
San Francisco.

My dear Doctor Warnshuis:

It is so fine to be able to end the year's bookkeeping for the library by adding the check for \$122.50 that you have just sent to us. We certainly appreciate the help that we have received from the California Medical Association.

All of the Library staff send many thanks and holiday greetings.

Very truly yours,

LOUISE OPHÜLS,
Medical Librarian.

Concerning prizes for essays on thyroid gland.

AMERICAN ASSOCIATION
FOR THE
STUDY OF GOITER

November 20, 1936.

To the Editor:—The American Association for the Study of Goiter again offers the Van Meter Prize Award of \$300 and two honorable mentions for the best essays submitted concerning experimental and clinical investigations relative to the thyroid gland. This award will be made at the discretion of the Society at its next annual meeting, to be held in Detroit, Michigan, June 14, 15, and 16.

The competing manuscripts, which should not exceed 3,000 words in length, must be presented in English and a typewritten double-spaced copy sent to the corresponding secretary, Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than April 1, 1937. Manuscripts received after this date will be held for competition the following year or returned at the author's request.

The committee who will review the manuscripts is composed of men well known in the fields of research and clinical investigation of problems related to the thyroid gland. At the last annual meeting of the Society the award for the year 1936 was presented to Dr. Edward Uhlenhuth, University of Maryland Medical School, Baltimore, Maryland, in appreciation of his manuscript entitled "Isolation of the Thyreosactivator Hormone from the Anterior Lobe of the Bovine Pituitary Gland." The committee also awarded honorable mention to Dr. E. Cowles Andrus and Dr. Donald McEachern, Johns Hopkins University and Hospital, Baltimore, Maryland, for their manuscript entitled "On the Nature of the Increased Metabolism in Hyperthyroidism."

The Association will publish the manuscript receiving the prize award in their annual proceedings, and reserve a place on the program of the annual meeting for presentation of the manuscript by the author, if it is possible for him to attend. This will not prevent its publication, however, in any journal selected by the author.

Very truly yours,

W. BLAIR MOSSER, M. D.,
Corresponding Secretary.

Concerning editorial on hospitalization plans.

To the Editor:—In your editorial, Hospitalization Plans in California, in your December issue, you write:

Of course, certain matters having to do with clinical laboratory and x-ray services, which today are everywhere accepted and demanded as concomitants of hospitalization, may need satisfactory adjustment; but the difficulties in regard thereto should not be unsurmountable.

The meaning and intent of this sentence is quite clear to those familiar with the subject, but since it will be read by many who are not, it would seem that the following facts are worth bringing to the attention of your readers. This editorial appears in the official journal of the California Medical Association; the House of Delegates of that Association has rendered its belief in no uncertain

terms that laboratory and x-ray services are just as much medical services as pediatric and surgical services; therefore, it might be fairer to state that the problem of furnishing these services on an insurance basis *must* receive some adjustment. The lines referred to also suggest that clinical laboratory and x-ray services are peculiar in being "concomitants of hospitalization"; are not medical and surgical services also concomitants of hospitalization? Finally, if one must be humanitarian, one must observe that the big health bill facing hospitalized citizens of moderate income is neither the hospital bill nor the x-ray bill; it is the surgical bill or the medical bill, and quite properly so. The operating surgeon, the family physician, the internist, devote untold time and energy to the care of their patients and deserve the fees they charge. However, from the point of view of the subscriber it would be very pleasant to have these fees also included in his benefits; to him they are just as much concomitant services as the radiologist's and justifiably much more costly.

Hospitalization insurance that provides hospitalization is both meritorious and desirable. Health insurance that provides medical care seems to be desired; the two should be clearly separated not only because hospitalization is the subject of your editorial, but also because the layman who directs the one may not be the ideal director of the other. I am

Yours very truly,

L. H. GARLAND, M. D.

Concerning space given to American Red Cross.

THE AMERICAN RED CROSS
NATIONAL HEADQUARTERS
WASHINGTON, D. C.

December 1, 1936.

California and Western Medicine,
San Francisco, California.

Gentlemen:—Please allow me to express to you, in behalf of our national officers, our very sincere appreciation for the generous contribution of space which you gave to the American Red Cross in CALIFORNIA AND WESTERN MEDICINE. It is only through the splendid cooperation which you and others give us each November that we are enabled to extend a universal invitation to all Americans to participate in Red Cross work through individual memberships.

Cordially yours,

DOUGLAS GRIESEMER,
Director of Roll Call.

Concerning State Health Board cooperation in campaign against syphilis.

STATE OF CALIFORNIA
DEPARTMENT OF PUBLIC HEALTH
SACRAMENTO

December 17, 1936.

F. C. Warnshuis, M. D.,
Secretary, California Medical Association.

Dear Doctor Warnshuis:

I desire to acknowledge your letter of December 16, designating the names of the committee appointed by the California Medical Association to cooperate with the State Department of Public Health in the campaign for the control of syphilis in this state.

We shall be most pleased to work with the committee, and solicit the interest of the members of the Association through said committee.

Very truly yours,

W. M. DICKIE, M. D.,
Director of Public Health.

Concerning new amputation, lower third of thigh.

To the Editor:—In the Journal of the American Medical Association for November 30, 1935, and in CALIFORNIA AND WESTERN MEDICINE, September, 1936, I described a new amputation in the lower third of the thigh.

This letter is an attempt to canvass the doctors within reach of these journals in order to evaluate through them the results obtained from this operation.

Information is desired on the following points:

Number of patients operated; mortality; condition for which the operation was performed; condition of the patient before the operation; complications.

I would appreciate discussion of any unusual difficulties which may have been encountered in the performance of this operation along the lines laid down in the above articles, also suggestions of changes in the technique which might be beneficial. Proper acknowledgment will be made for the use of case histories submitted.

MEDICAL JURISPRUDENCE†

By HARTLEY F. PEART, ESQ.

San Francisco

Are Municipal Ordinances Imposing a License Tax Upon Physicians Valid?

A great number of cities and towns in California have ordinances under the terms of which all physicians engaging in practice within their respective boundaries are required to secure licenses—ostensibly for the privilege of engaging in the practice of medicine and surgery. In each of these ordinances the only requirement for a license is the payment of a prescribed fee. Within the past two years the legal department of the California Medical Association has received requests for opinions on the subject under discussion from members of the Association practicing in a number of different municipalities, including San Francisco, Modesto, Petaluma, and Isleton. In view of the number of inquiries received, it has occurred to us that a discussion in this column of licensing ordinances, in so far as they may apply to the medical profession, would be appropriate.

The power of a city or town to impose a license tax upon physicians for the privilege of engaging in the practice of medicine within the municipality is subject to certain limitations. In order to discuss these limitations it is necessary preliminarily to state that there are two types of license tax. The first type is a license tax imposed for the purpose of defraying the cost of inspection and regulation of the business or profession subjected to the tax. The second type is one solely for the purpose of raising revenue for the general expenses of the municipality.

The first type, that is, a license tax for the purpose of inspection and regulation, is within the power of all municipalities (Political Code, Sec. 3366) subject to a specific limitation, namely, that the license tax may only be levied upon those businesses and trades which are subject to the police power. Any business, trade or profession which may not be inspected or regulated by the municipality under its general police power may not be subjected to a license tax which has as its sole purpose the defraying of the cost of inspection and regulation. The medical profession as such is not subject to inspection and regulation by municipalities and, therefore, it falls within the limitation under discussion. In *City of Sonora vs. Curtan*, 137 Cal. 583, our Supreme Court held that the city of Sonora lacked power to impose a license tax upon attorneys-at-law for the purpose of defraying the cost of regulation and inspection. In *City of Redding vs. Dozier*, 56 Cal. App. 590, it was clearly indicated that the same rule applies with respect to the medical profession. Therefore, we may conclude that municipal licensing ordinances which have for their purpose the defraying of inspection and regulation costs are invalid in so far as they attempt to impose a fee or tax upon physicians practicing within the community.

With respect to the second type of license tax, that is, a license tax for the purpose of raising revenue, a some-

† Editor's Note.—This department of CALIFORNIA AND WESTERN MEDICINE, containing copy submitted by Hartley F. Peart, Esq., has been established by the California Medical Association Council. Each issue will contain excerpts from and syllabi of recent decisions and analyses of legal points and procedures of interest to the profession. These will be compiled by Hartley F. Peart, General Counsel of the Association.

what different principle governs. A license tax for the purpose of raising revenue may not be imposed by any municipality upon any business, trade or profession unless the State Legislature has by statute expressly delegated to the particular municipality concerned the power to impose such a tax. There are a number of cities and towns in the State which have never received authority from the Legislature to impose license taxes for the purpose of raising revenue. On the other hand, by statute, all of the cities of the sixth class are authorized to raise revenue by means of imposing license taxes upon any business, trade or profession. Likewise, the Legislature has approved a number of city charters which contain specific authorizations to license for the purpose of raising revenue. It is impractical here to attempt to enumerate all of the California cities and towns which have received legislative authorization and those which have not.

If a particular municipality has been authorized by the Legislature to impose license taxes for revenue-raising purposes upon all business, trades and professions, then in that event a municipal ordinance imposing a license tax upon physicians is valid and enforceable.

In determining whether or not a particular municipal ordinance imposing a license tax upon physicians is or is not enforceable as against the physicians in the community, one must be able to answer two separate questions: (1) Is the ordinance imposing the tax a revenue-raising measure or is its sole purpose that of defraying the cost of inspection and regulation; and (2) If it is a revenue-raising measure, has the Legislature conferred specific authority upon the municipality to impose license taxes upon the professions for revenue purposes?

Expert Witnesses in Malpractice Cases May Not Be Required to Give a Yes or No Answer to an Hypothetical Question and Must Be Allowed to Explain Each Answer.

On November 7, 1936, the District Court of Appeal for the Second Appellate District decided the case of *McGuire vs. Dr. Marion W. Baird*, 87 C. A. D. 436. From the opinion of the court it appears that the case was a malpractice action against a physician and that during the course of the trial one of the attorneys propounded a somewhat lengthy hypothetical question to a physician, who had qualified as an expert witness. Upon the insistence of the attorney who had propounded the question the trial court ruled that the witness would have to answer it either "yes" or "no," and that the witness could not give a qualified answer or an explanation of the reasons for his answer. On appeal before the District Court of Appeal, it was held that the trial court committed prejudicial error in refusing to allow the expert witness to qualify his answer and give such explanations therefor as he saw fit.

Inasmuch as it is possible for an attorney so to phrase a lengthy hypothetical question that the witness cannot conscientiously and honestly answer the question either "yes" or "no," but must, in order to tell the truth, qualify his answer and state his reasons therefor, it is important to remember that under the law a physician who is on the witness stand as an expert witness cannot be forced to answer a hypothetical question "yes" or "no" when, in his opinion, an explanation is necessary.

SPECIAL ARTICLES

PARIS EXPOSITION WILL DEVOTE SECTION TO MEDICINE AND SCIENCE

A liberal education in the field of modern medicine and a comprehensive survey of resultant achievements will be one of the many interesting attractions at the Paris 1937 International Exposition.

According to present plans announced by the French High Commissioner, three huge pavilions will be devoted to this unusual display. Special emphasis will be placed on the precise scientific character of modern medicine as

compared with the hit-or-miss methods of the nineteenth century. The exhibit which naturally will be of great interest to all members of the medical profession and its allied fields, will be so arranged and displayed as to be easily understood by the layman.

The three great halls, each reverently dedicated to a great name in French medical history, will be devoted to the illustration of the various phases of medicine and its allied sciences. The Claude Bernard Pavilion, so named in honor of the great pioneer in physiology, will contain among many other unique exhibits, a transparent man, illuminated to show the glands, nervous system, and general anatomy. Another of the exhibition halls will be called Laennec Pavilion, to perpetuate that name, noted as a creator of clinical medicine and the inventor of auscultation, which is a method of diagnosis concerned with the sounds produced by the human body. In this building will be shown a remarkable and important collection of instruments, books and relics of nineteenth century medicine. Along with this will be a display of modern medical instruments and equipment, illustrating the advances of the past fifty years in the science of medicine. Such exhibits will be chronologically arranged to demonstrate the steps in medical progress from the dark ages of ignorance, through the enlightenment of experimentation and research, into the brilliancy of modern scientific methods and achievements.

Every branch of medicine will be represented and treatment for certain diseases will be demonstrated in many cases. Moving pictures will be employed to show scientific experiments, research into causes of infection and illness, and methods of treatment. Everything possible will be done to clarify in the mind of the layman the scientific and technical accomplishments of modern medicine.

In addition to presenting a comprehensive view into medical history and present-day practice, this exhibition will offer a remarkable insight into the probabilities of the medical science of the future. The strides which scientific research is making in the conquest of illness will be demonstrated. Government regulation of sanitation will be stressed in the light of its importance in the fight for world-wide health and happiness and the necessary contribution of industry to the elimination of disease will be emphasized.

Illustrations will clarify the gradual elimination of the age-old barriers between medicine and the allied sciences which have stood in the path of progress since the days of medicine's first crude efforts. The debt to chemistry and physics will be explained, without whose coöperation we would still lack such important curative and diagnostic agents as radium and the x-ray. The endless collaboration of energies working for the benefit of mankind will be described, and civilization's hopes in the never-ending struggle against disease and death will be indicated at the Paris Exposition next May.

NATIONAL SOCIAL HYGIENE DAYS

Plans for the first National Social Hygiene Day, to be held February 3, 1937, are announced by the American Social Hygiene Association of 50 West Fiftieth Street, New York City. On this day, state and community voluntary organizations interested in the control of syphilis and gonorrhea and other social hygiene problems, with the advice and approval of health authorities and the medical and allied professions, are planning to hold meetings all over the United States.

In New York City the American Social Hygiene Association will hold its annual meeting on February 3. Also the Social Hygiene Council of Greater New York will hold its fifth annual regional conference at the Hotel Pennsylvania on the same day. It is expected that public leaders, including Surgeon-General Parran, President Ray Lyman Wilbur of Stanford University, President of the American Social Hygiene Association and former Secretary of the Interior, will speak to these meetings. National agencies and many of their state and community organizations which include social hygiene activities in their yearly programs are planning to participate. It is probable that a nation-wide radio hook-up will provide

addresses of great importance from high government officials and civic leaders in different parts of the country as a climax to the activities of the First National Social Hygiene Day.

There has been definite progress all along the line during the past year in public understanding and support of the campaign against syphilis. Newspapers and magazines are opening their columns to public discussion of this health menace to a greater extent than ever before. Certain important groups, such as the General Federation of Women's Clubs and the National Council of Women, are adopting the fight against syphilis as among their next major efforts in promoting community health. (The women's groups are particularly interested in the elimination of prenatal or congenital syphilis, which, acquired by a child before birth from an infected mother, is responsible for a large share of stillbirths, miscarriages, and defective children, and which is entirely preventable by proper treatment.)

Service luncheon clubs, such as Rotary, Kiwanis, and Lions, have recently been undertaking social hygiene programs. Business leaders are studying the cost to industry from lost time, lowered efficiency and hospitalization, due to syphilis. The large insurance companies are concerned over the unnecessary claims for death and disability due to syphilis. Civic clubs, forums, and town meetings are discussing the diagnosis and treatment of syphilis as a national plague.

It is believed that the direction of united nation-wide attention to this subject in the way that is proposed will help professional and lay community leaders to capitalize and increase this new interest, and consolidate for further advance toward meeting General Parran's challenge to "stamp out syphilis."

MUTATION AND THE ORIGIN OF CANCER

Some years ago Boveri advanced the theory that cancer cells were those in which the tiny microscopic bodies called chromosomes were abnormally distributed. In every normal body cell there is contained a definite fixed number of chromosomes which is characteristic of the species. Thus, in every normal body cell of a man there are forty-eight, and in every normal body cell of a mouse forty of these structures.

Boveri noticed that in certain cancers there was an abnormal distribution of chromosomes, during cell division in many of the cells. As a result of this, there were cells formed in which a great excess of chromosomes occurred. There were also cells formed which were deficient in chromatin material. Boveri looked upon the abnormal distribution as the cause of cancer.

As time passed, evidence against his hypothesis was derived from two sources. The first, of an indirect but interesting nature, came from genetics or the study of heredity. Blakeslee, Belling, and others, working with the jimson weed, *Datura*, showed that markedly abnormal distribution of chromosomes could be obtained without resulting in anything resembling tumorous or cancerous growth. They further showed that cells or plants in which the distribution of chromatin was asymmetrical or unbalanced were distinctly less vigorous and died at a much earlier age than did normal ones. Since cancer is characterized by an immense vitality and growth energy, this evidence did not look at all promising for Boveri's theory.

It was not, however, until workers with tissue culture were able to observe the living and dividing cells of rat and mouse cancer that direct evidence on Boveri's hypothesis could be obtained. In a number of different tumors it was found that cells with asymmetrical distribution of chromatin divided much more slowly than the cells in the same tumor which had the normal number of chromosomes. As a result the abnormal cells were certain to leave fewer descendants than were the normal cells. The tumor would, therefore, constantly tend to show a steadily increasing proportion of normal cells and the cause and effect relationship of abnormal chromosome distribution and cancer formation is entirely broken down.

In spite of this fact Boveri did science a great service by providing those who felt that the significant difference between a cancer cell and its normal forbears was some sort of change within the cell itself, a theory that could be actually tested. In the development of the interest which his hypothesis aroused, research workers naturally focused their attention on other biological processes which might possibly serve to explain the nature of the change from a normal to a cancerous cell.

Among the most promising of the tentative hypotheses advanced was that of Tytzer, who in 1915 pointed out that the change under consideration fulfilled the conditions encountered when a process known as mutation occurred. He recognized frankly that the theory which he suggested was extremely difficult of experimental test, but offered it for what it was worth and to stimulate discussion. This it certainly did, for at intervals during the past twenty years other investigators have independently advanced the same theory.

The term "mutation" means sudden change. It was first given an important rôle in the process of evolution by a Dutch botanist, de Vries, in 1900. De Vries believed that evolution proceeded most commonly by a series of sudden discontinuous variations which were perpetuated by inheritance and were, therefore, essentially permanent.

For some years there was not sufficient knowledge of the process of heredity available to determine what the relationship between the appearance of a mutation and the presence of chromosomal changes might be. Then, by the work of Morgan and his associates and by utilizing the hypothesis of hereditary units suggested by Cuenot, the whole problem began to assume a more integrated and consistent form.

The simplest hereditary units called "determinants" by Cuenot were given a shorter designation, "genes," by Johannsen. They were found by Morgan and his co-workers to be closely associated with the chromosomes and to act as though they were arranged in a linear series in or on the individual chromosomes. Their relationship to one another was shown to be fixed, measurable, and predictable.

Mutation of the sudden and permanent change of these genes became a problem capable of some degree of experimental control and investigation. It was found that certain physical and chemical factors increased the rate at which the sudden changes or mutations occurred. These factors could be varied experimentally. The whole question took on a new and more general importance.

It soon became evident that sudden and permanent changes in the smallest hereditary units or genes were not the only type of mutations which occurred and which could be induced. The work of Blakeslee and Belling, to which reference has already been made, gave clear evidence that whole chromosomes could be doubled or even quadrupled and that, therefore, new numerical chromosome combinations could be made. When this occurred suddenly and was handed down by heredity and conditions of a mutation were fulfilled and the definition of that process had to be extended.

Gradually it became clearer that, between the chromatin material of the cell and its surrounding cytoplasm or cell substance, complicated relationship existed which might be suddenly and permanently disturbed and altered. We do not yet know the relative importance of chromatin and cytoplasm in the origin and perpetuation of these changes. It seems, however, more than possible that in the sudden appearance of one or more changes of this mutational sort may be found the origin of the biological variation in the type of cellular behavior known as cancer.

Such a change or changes might result from any one of a number of influences. The so-called carcinogenic agents, which are almost monthly increasing in number, may be one category of stimulative factors. A group of internal secretions as yet incompletely analyzed, occurring naturally in the body, may provide another source of potential interest as possible mutation-increasing substances. There may be and probably are many others as yet undiscovered roads to increased mutation rate. Cancer research of the future has these problems before it. In the meantime the conception that the cancer change itself

may be a mutation excludes no existing evidence and provides a consistent and attractive working hypothesis by which important advances should be made.—*Bulletin of the American Society for the Control of Cancer.*

CANCER DEATH RATE FOR 1935 HIGHEST ON RECORD*

In a recent analysis of deaths from cancer, Frederick L. Hoffman, LL. D., Biochemical Research Foundation of the Franklin Institute, Philadelphia, points out that the cancer death rate for 184 cities with a population in 1935 of nearly 46,000,000 was 125.6 per hundred thousand of population against a rate of 123.1 in 1934, establishing the highest death rate from this cause since records have been carefully observed. The actual number of deaths in the 184 cities increased from 55,201 in 1934 to 57,309 in 1935, while 107 cities reported increases and seventy-seven decreases in their cancer death rates. The ten cities with the highest cancer death rates were Madison, Wisconsin, 286.8; Concord, New Hampshire, 238.4; Portland, Maine, 229.4; Pasadena, California, 218; Troy, New York, 187.6; Boston, 187.3; Shreveport, Louisiana, 185.2; Pittsfield, Massachusetts, 183.5; Spokane, Washington, 182.8, and Quincy, Illinois, 178. In the five largest American cities, Chicago, Detroit, Los Angeles, New York, and Philadelphia, the highest rate (147.5) was returned for Philadelphia. Detroit was the only city in this group to show a decrease (67.8). Presenting comparative rates in certain foreign countries, Doctor Hoffman points out that Switzerland reported an increase from 115.8 per hundred thousand of population in 1907 to 147.3 in 1934. Death rates, based on specified types, were 43.2 per thousand for cancer of the female genital organs in single women (25 years old and over), compared with 64.6 for married, widowed and divorced women. For cancer of the breast the rate for single women was 54.6, and for married, widowed and divorced women it was 49.1.—*Bulletin of the American Society for the Control of Cancer.*

BLINDNESS AND ITS CAUSES**†

It was with some misgiving that I accepted the assignment of reporting to you some facts about blindness. Available source data are scarce and in many respects unreliable, and unfortunately I do not belong to the group of statisticians who enjoy making estimates that resemble rabbits drawn out of the magician's hat. However, if you are willing to accept the statements for what they are—mere indications of the probable truth—and will focus your attention as much upon what it might be desirable to know as upon what we already know, perhaps I can give you a general background of information.

But why analyze blindness? There are two reasons why analysis is important. In the first place, for the sake of the individual who is blind or potentially blind, it is important that everything possible should be known about his condition. That this is so can be shown by the following case, which is illustrative of many that are to be found in the records of commissions for the blind and schools for the blind. . . .

Our second reason for desiring thorough analysis of cases is that the facts concerning them may be summed up to produce for administrators, who are planning prevention of blindness and work for the blind, the necessary basis for sound planning. For example, the acceptance of routine Wassermanns of pupils in schools for the blind is partly attributable to group statistics showing syphilis to be an important cause of blindness among children.

How shall we analyze blindness? What are the essential facts?

* J. A. M. A., October 3, 1936.

**Address by Miss C. Edith Kerby, Statistician of the National Society for the Prevention of Blindness, at the annual conference of the Society in Columbus, Ohio, afternoon session, Friday, December 4, 1936.

† Under the program of the Social Security Act, commonwealths wishing to receive federal aid in the care of the blind will be expected to keep accurate records. The California Department of Public Welfare is making a study of possible revisions of its examination form blanks.

Perhaps the most frequent question which has come to me concerns the number of blind in the United States or in some particular section of the country. On this point, the enumeration made in 1930 by the Bureau of Census gives the figure 65,431. However, this is admitted by the Bureau of Census to be an understatement. Consequently, in the same year also, the American Foundation for the Blind attempted to estimate the true figure by comparing census figures with registers kept by commissions for the blind in certain states, and arrived at the figure 114,000. Even this figure is open to question, chiefly because the various states differ in their concept of who is to be considered blind.

This brings us to our next point of analysis. If we are to secure data that is worthy of the name "statistics of the blind," we must consider how we shall define the term "blindness." One possible approach to this problem is that all states shall be brought into agreement on the definition of blindness. At the present time, among the thirty-three states having blind relief laws, there are ten which define blindness in terms of degree of vision, but there are seven different degrees, varying all the way from "loss of both eyes" to "visual acuity of 20/200." Fifteen additional states use indefinite statements such as "vision insufficient for tasks for which eyesight is essential." The remaining states have no definition mentioned in their laws. In spite of this variation, there is apparent at the present time a tendency to set the dividing line between the blind and the seeing world at visual acuity of 20/200, and to include in the blind group also individuals who have a peripheral field defect which limits the field of vision to an angular distance no greater than 20 degrees.

Even with a reasonably uniform definition of blindness, it is important to have some knowledge of the varying degree of visual handicap included among "the blind." The man on the street, with no knowledge of the problems involved, will define a blind person as "one who cannot see," by which he usually means an individual who is totally blind or who has light perception only. As a matter of fact, this description would cover about one-half to two-thirds of the persons usually considered blind. Among the recommendations of the Committee on Statistics of the Blind is a classification by degree of blindness which calls for five groupings. In Group 1 are those who are totally blind or who have mere "light perception." In Group 2 are those having "perception of motion" or only a negligible amount of "form perception" (under 5/200). Group 3 covers those having "traveling sight" (visual acuity of 5/200, but not 10/200). Group 4 includes those able to read large headlines (visual acuity of 10/200, but not 20/200). Group 5, or "the border-line" group, includes those having visual acuity of 20/200, and also those whose central visual acuity may be better than 20/200, but who have another visual defect—usually limitation of fields.

In analyzing a case of blindness, vision tests should be sufficiently accurate to enable us to classify the case in accordance with a scheme such as the one outlined. This knowledge of the degree of handicap is of interest not only to the statistician, but also to the administrator or case worker who may wish to use it as a guide in solving training or placement problems. It goes without saying that the ophthalmologist is obviously the best person to make an adequate determination of degree of vision.

The chief reason for selection of an ophthalmologist to give the eye examination, however, is to insure an adequate diagnosis. To be adequate, a diagnosis should indicate not only the part of the eye affected and the nature of its disorder (topographical factor derived from the Greek words meaning "to record the place"), but also the underlying cause of the eye condition (etiologic factor from the Greek "study of causation").

Wherever we have been forced to rely upon the records of old examinations, or upon recent examinations of cases which have occurred years ago, we have found practically no information as to etiology available. As a matter of fact, only the more recent studies of causes of blindness tend to give any etiologic data, although, oddly enough, the older studies did make reference to certain etiologies, such as accidents. With the gradual adoption of the cause of blindness classification of the Committee on Statistics of

the Blind, we are beginning to acquire statistical data on causes of blindness in which the cases are cross-classified both by topographical and etiologic factors. Much more time and emphasis need to be placed upon gathering such cause data.

The major responsibility for examination necessarily rests with the ophthalmologist, but nurses and case workers in general can make a noteworthy contribution, first by educating the public to the importance of eye examination; second, by referring suspected cases for examination at the time of occurrence of blindness, or preferably before; and third, by gathering for the examining physician authentic facts about the histories of the cases.

Although, as I have indicated, existing information is far from complete and satisfactory, it may be of interest to note the following facts indicated by available data. Causes of blindness will be classified under the two headings mentioned above.

Cause of Blindness—Etiologic Factor

1. The most numerous group in any table at the present time is invariably the "unknown." Fully 40 to 60 per cent of all cases fall into this group. . . .

2. Of the known causes, the most important group is that of the infectious diseases which account for from 15 to 25 per cent of the cases.

Syphilis and ophthalmia neonatorum (babies' sore eyes) are the most important diseases in this group. Although figures are particularly incomplete for syphilis, this disease is probably responsible now for more new cases of blindness among children than is ophthalmia neonatorum, and the figure for cases occurring among adults may be much larger than that for children. If the recently organized antisiphilic campaign proves effective, we may see within the next generation the same spectacular reduction in blindness from syphilis which has occurred during the past thirty years in the case of ophthalmia neonatorum (incidence has been reduced 75 per cent since 1907).

Other significant causes included in the group of infectious diseases are trachoma, meningitis, septicemia, tuberculosis, scarlet fever, measles, smallpox, and diphtheria. No one of these causes looms very large, with the possible exception of trachoma which, as you know, is very prevalent in some sections of the country and practically nonexistent elsewhere.

3. Accidents form the next largest group, being responsible for 15 per cent or more of blindness. Unfortunately a large proportion of the cases are indefinitely specified merely as trauma. Hence it is impossible to give any satisfactory analysis of the causes of eye accidents.

4. The congenital and hereditary cases are probably responsible for about 10 per cent of blindness in the general population. Among the child population this is, however, the most numerous group. In the current studies of causes of blindness among children made by the Committee on Statistics of the Blind, 50 per cent of the cases are attributed to these causes, although it is felt that at least a portion of the cases should more properly be classified under congenital syphilis. Moreover, our congenital cases need further study to determine whether the condition is hereditary or could be prevented by proper prenatal care.

5. The remainder of the cases are divided among the noninfectious systematic diseases, such as vascular diseases, nephritis, diabetes, etc., and the neoplasms and toxic poisonings. In our present statistics, less than 5 per cent of the cases are attributed to noninfectious systemic diseases. Undoubtedly, this group will prove much larger when causal relationships have been more definitely established by the medical profession.

Causes of Blindness—Topographical Factor

1. About one out of four cases of blindness in the general population appears to be due to cataract. The cases are mostly of the senile type, but congenital and traumatic cataracts are also included. In view of the fact that surgical treatment of cataract is possible, and generally successful in uncomplicated cases, the existence of this large group of individuals with cataract presents a challenge to

case workers, such as public health nurses. Undoubtedly, there are many whose condition might prove to be amenable to corrective treatment.

2. Optic atrophy ranks second on the list. It includes about 15 to 20 per cent of the cases. The etiologic factor is not mentioned in most cases. However, indications are that the most important single cause of this condition is syphilis, with trauma, meningitis, neoplasms, and non-infectious diseases responsible for the remainder.

3. Glaucoma causes more than 10 per cent of blindness. Its etiology has not as yet been established and, as you know, the only hope for preventing blindness from this disease lies in medical supervision which is instituted early and carried out continuously throughout life.

4. Disorders of the choroid and retina account for about 10 per cent of blindness. Perhaps degeneration of the retina, which is usually considered hereditary in origin, is the largest single cause in this group. The group also includes detachment of retina as well as various inflammatory and atrophic conditions of these membranes. The latter are frequently designated as associated with infection, although the nature of the infection is not specified.

5. Affections resulting in opacities of the cornea (largely ophthalmia neonatorum, syphilis, and, in some places, trachoma) are responsible for about 10 per cent of blindness.

6. Developmental anomalies and degenerative changes in the eyeball account for another 10 per cent. The former are congenital in origin, and most of the latter are associated with trauma.

7. Uveitis and affections of the iris and ciliary body rank next with more than 5 per cent, these cases being attributed to infections and trauma.

8. Refractive errors, chiefly myopia, account for only a small percentage of blindness (under 5 per cent in this country, but it is interesting to note that European figures show a much higher incidence).

Age at onset of blindness should also be determined as definitely as possible at the time of the eye examination. Frequently, the ophthalmologist will welcome investigation by the nurse or case worker on this point. It may not be an easy matter to determine the exact age at which the individual loses his sight. Nevertheless, it is helpful to try to do so, since the ophthalmologist may be guided by this information in making his prognosis, the worker for the blind will use it in determining the need for special training, and, finally, to the statistician, it supplies a fact which is valuable in itself as well as useful in determining trends. Although information on this point is quite as incomplete and inaccurate as that on causes of blindness, it may be of interest to quote the figures given in the 1920 census. If we weigh the ratios given in that report according to the Foundation's estimate of the true total, we find that the incidence of blindness among children under five years of age is about two in ten thousand. The rate falls off during the preschool, school, and the adolescent ages, but again reaches two at about the age of thirty-five. It increases up to the age of sixty, when it is about nine in ten thousand, and very rapidly thereafter until it reaches a very high rate of seventy-five in ten thousand at the age of eighty or over. At first glance, these figures seem to confirm the popular theory that if one lives long enough, he may become blind. (The chances are 1 in 130 for persons over eighty years.)

The ophthalmologist's examination will ordinarily include his prognosis and more or less definite recommendations for care and treatment to restore or preserve vision, when this is possible.

If all of these essential facts concerning the individual's eye condition are noted on his eye examination record, the particular type of record form that is used is immaterial. However, it may be desirable to call attention to the suitability of the eye examination form prepared by the Committee on Statistics of the Blind for this purpose. (This form is at present undergoing a slight revision which was decided upon at the time that the Social Security Board was developing its recommended form which is modeled closely on that of the committee.) Its items call for factual information summarized in a form which lends itself readily to tabulation.

One further word of warning concerning the statistics which I have given. They are based on a comparative analysis of such data as are available. The figures are, as I have said, essentially incomplete and too much faith should not be placed in their accuracy. It is highly desirable that the statistics which have still to be compiled shall have a much higher degree of uniformity in order that the findings of various studies may be combined and compared. It is for that reason that I have made a special point of stressing the recommendations of the Committee on Statistics of the Blind, which set a pattern for minimum standards, and can be expanded further as experience shows this to be necessary.

Throughout the country there is a renewed interest in the problems of the blind and of prevention of blindness due in part to the expanding of state budgets through federal grants. This seems to offer hope that we may reach our objective—a complete analysis of each case of blindness, to the end that each shall have adequate examination and treatment necessary to give maximum possible vision, and an adequate summary of facts concerning all cases of blindness.

PROTECTION OF CHILDREN FIRST AIM OF FEDERAL CAUSTIC POISON ACT

Fines were recently assessed against a number of manufacturers and distributors, including ten druggists and paint dealers, in the District of Columbia, for selling caustic or corrosive materials in containers which did not meet the labeling requirements of the Federal Caustic Poison Act, report officials of the Food and Drug Administration, United States Department of Agriculture.

Such common household articles as lye, used in softening water, cleaning out drains and kitchen sinks, or ammonia used in cleaning, are dangerous poisons and by law must be labeled as such. Children cannot be expected to read such labels. The products should invariably be stored in a safe place and especially should be kept well out of the reach of children.

Two recent examples of such poisoning have been widely publicized. A small boy in Chicago and another in Washington, D. C., each swallowed lye enough to sear the tissues of the throat and esophagus or gullet, until death by starvation appeared certain because the walls of the passage were healing shut. Both are on the road to recovery as treatment—in one case with a string of small rubber balls, and in the other with a string of small beads—is gradually opening the scarred tissues of the throat as the boys swallow the beads and rubber balls each day. By withdrawing the swallowed objects the physicians are keeping the passages open and are gradually enlarging them as they heal.

Through the efforts of the American Medical Association and other interested persons and organizations, Congress passed the Federal Caustic Poison Act on March 4, 1927, for the purpose of insuring the use of poison labels on the dangerous products and thus putting users on their guard. Enforcement of the Act was assigned to the Food and Drug Administration.

The law applies to the following substances in the percentages noted, or more: Hydrochloric acid, 10 per cent; sulphuric acid, 10 per cent; nitric acid, 5 per cent; carbolic acid, 5 per cent; oxalic acid, 10 per cent; any salt of oxalic acid, 10 per cent; acetic acid, 20 per cent; hypochlorous acid or its salts, except chlorinated lime to yield available chlorine, 10 per cent; potassium hydroxid, 10 per cent; sodium hydroxid (caustic soda and lye) 10 per cent; silver nitrate, 5 per cent; and ammonia water, 5 per cent.

There are four distinct markings which must appear conspicuously on the label to meet the specifications of the Act. They are as follows:

1. The word "poison" must be printed in uncondensed Gothic capital letters. These letters must be at least one-third of an inch high if the trade name or any other word on the label contains a letter this large. If there is no letter this large, the "poison" must not be smaller than the largest letter.

2. Directions for treatment of the poisonous substance must be stated on the label. The Food and Drug Ad-

ministration has published antidotal treatments for each of the twelve caustic or corrosive substances covered by the Act. They are intended primarily to relieve the patient until a physician arrives to administer more thorough treatment, if necessary.

3. The common name of the caustic or corrosive substance must be printed on the label. This not only is informative for those who use it in the home, but it is of particular value to the physician, as he can give immediate medical attention.

4. The label also shall bear the name and place of business of the manufacturer, packer, seller, or distributor.

Legal labeling, officials of the Food and Drug Administration feel, will serve as a caution for parents in storing such poisonous substances out of reach of small children. A small child has little sense of taste and is likely to put into his mouth anything that he can get into his hands.

The cases against the ten druggists and paint dealers in the District of Columbia were based on sales of oxalic acid, acetic acid, and ammonia water, without the labeling required by the law. The cases were first offenses on the part of the defendants, and apparently for this reason the court, after each had entered a plea of guilty, imposed a nominal fine of \$10 in each case. The statute provides for a fine of not more than \$200 or imprisonment for not more than ninety days, or both.

SOCIAL WORKERS PLAN UNION*

The first trade-union of social workers ever set up in the United States will shortly be organized in New York under a charter from the American Federation of Labor.

The move represents a decision by the Federation to create like unions in other cities and, eventually an international union. For the present, the New York union and others that may be set up in other cities will operate as federal locals, directly affiliated with the Federation and subject to a measure of control by the parent body.

FOLLOW PRACTICE

This follows the fifty-year practice of the Federation in first organizing local unions more or less in leading strings until a sufficient number have been organized to permit the setting up of an international union with full and complete autonomy.

William Collins, general organizer of the Federation in charge of the New York area, who did the pioneer work of organizing the automobile workers of Detroit, while admitting that plans for organizing New York are well under way, declined to go into details, saying:

"There is considerable yet to be done. But is there any reason why these people should not be organized and in the Federation?"

RECOGNIZES CONDITION

The decision of the Federation to organized social workers is a recognition of changed conditions, persons intimate with the practices of the Federation said.

Hitherto, the Federation has not considered the social worker organizable material, and the social worker, usually pretty much of a lone worker, has not looked with kindly eye on organization, and especially under American Federation of Labor auspices. Such organizations as they have had have been more in the nature of clubs and social organizations than unions.

NEED APPARENT

During the depression, however, when social work expanded into almost an industry, the need of organization became more apparent. On the part of the labor leaders, with whom the social workers came into much more intimate contact than before, old prejudices vanished, and their place in the labor movement became apparent.

There are several organizations of social workers now in Greater New York, each working independently of each other. It is expected that most of these will merge with the new union.

* From a news dispatch by John J. Leary, Jr., in the *Los Angeles Examiner*.

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. X, No. 1, January, 1912

From Some Editorial Notes:

The Second Decade.—The year 1912 brings to a close the first decade in the life of the reorganized State Society, and also of the *California State Journal of Medicine*. Some of the years—particularly the early ones—were, to put it mildly, stormy; bad weather was the prevailing condition. So many things happened, so uphill was the work and so constantly did the stones for building roll down hill a bit upon the slightest provocation, that one thought came to be the regular daily opening of consciousness: "What will happen next?" The question did not arise, "Are we in debt?" It was always, "How much do we owe?" The early years were indeed rough and stormy. We were fighting for the promotion of a few truths, and to get any truth disseminated demands repetition, reiteration—hammering home. In the hammering process, someone would occasionally get hurt; libel suits in plenty were threatened; a few were actually filed; none ever came to trial. With the close of the decade we find a great change; comparative quiet has followed the storm, though occasionally there is a little disturbance; we no longer ask, "How much do we owe?" but with confidence say, "What is the bank balance today?" That helps a good deal! But because the Society is in good condition and fairly prosperous, let us not for a moment think that the work is done. The foundation of the building is built fairly strong; now let us, during the next decade, see that the good, solid building operations continue; let us continue the work until we have a really complete and thoroughly well-built State Society; one that is so strong, so valuable to its members, so active and so continuously alive to their interests and for the public welfare, that no practicing physician in the State can afford *not* to be a member. . . .

By His Work.—Elsewhere in this issue of the journal will be found a résumé or abstract of some documents published as Bulletin No. 22 of the Los Angeles County Medical Association. Senator Works, the distinguished Eddyite representative in the United States Senate, took several hours of the nation's time to address the Senate more or less on the subject of his health, that of his wife, and the health and habits of his son, the inefficiency of "regular" doctors. . . .

Extra-Medical Proselyting.—In these days when publicity on large questions seems to be the tendency of the hour, it is of great interest to the medical world to note that trend, in so far as it affects medical affairs. Our profession and medical considerations in general have certainly not suffered from lack of the calcium ion which illuminates. Doctor Wiley, "Christian Science," the Owen bill, tuberculosis work, vivisection, etc., are very much battered subjects, and our own good Senator Works (not Senator Good Works) has had a pretty bit of notoriety thrust upon him by his tampering. All these mental pabula, however, have been served without anything to make them savory, until of late there have appeared from the pen of a brilliant Frenchman, Brioux, two plays which deal with hot coals, these burning subjects being the problem of artificial abortion, and our old friend, syphilis. One play is called "Maternité," the other "Les Avaries," or, as Mrs. Bernard Shaw has translated them, "Maternity," and "Damaged Goods." . . .

A mere recital of the stories seems bald and unspeakably ugly, but the author has employed an artistry born of genius, and the plays are achieving a tremendous vogue abroad. Here at last we have some medical matters brought to our notice in a form more compelling to the

(Continued in Front Advertising Section, Page 17)

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By CHARLES B. PINKHAM, M.D.
Secretary-Treasurer

News Items

"Healers of every sect, physicians, osteopaths, chiropractors, and all the rest are taking a basic science examination in Arizona under a law recently passed. The medical doctor is not examined on medicine nor the chiropractor on chiropractic, but both are required to show what they know about the structure and processes of the body on which they practice. They are examined on anatomy, bacteriology, chemistry, hygiene, physiology, and pathology. There are no sects on any of these sciences. The muscles and bones are in the same places and chemical processes react in the same way, whether one is a physician or a naprapath. But if one is to deal professionally with these structures and processes, by whatever theory, he should know where and what they are and how they work, normally and abnormally. We require that knowledge in one who operates or repairs engines; it is at least equally indispensable to one who undertakes the same responsibilities with living human bodies. Mental healers, by this law, are exempt. Since they treat abdominal pain by appealing to the mind, it is not necessary for them to know where the stomach and the appendix are, or to be able to distinguish which one of them it is that hurts. It would seem that this requirement is the very least which the State owes, for the protection of its citizens against ignorance. So long as there are persons who believe that there are sects, in the art of healing, the law must recognize those sects and permit all qualified persons to practice them. But that qualification is based on these basic sciences, without which a practitioner would be like an automobile mechanic who did not know that the cylinder contained pistons which were operated by the explosion by electric spark of gasoline vapor and air. Mere fidelity to a theory is no substitute for information and no mitigation of ignorance. The Arizona experiment will be followed with interest." (San Francisco Chronicle, December 16, 1936.)

"Continuing their Pacific Coast clean-up of syndicates and persons conducting fraudulent enterprises through the mails, United States postal inspectors at Los Angeles last night announced arrest of Lewis Levy, charged in a Wisconsin indictment with participating in a variation of the 'eyesight racket.' Federal men said a group with which Levy was connected guaranteed to remove cataracts from patients' eyes at fees ranging from \$500 to \$1,000. The 'medical' group's headquarters is at Milwaukee. Levy was held in \$15,000 bond, pending removal proceedings." (Sacramento Union, December 7, 1936.)

"Two women, charged with aiding illegal operations as members of a coast-wide ring recently shattered by indictment of thirty-one persons, won clemency before Superior Judge Steiger yesterday. The pair, Mary Wilson and Leola Habel, were allowed to plead guilty to a misdemeanor carrying a sentence of less than a year in the county jail, and a hearing of their plea for probation was set for December 8. The court also quashed fourteen of thirty-one indictments returned here against doctors and civilians connected with the ring which functioned also in Los Angeles, Long Beach, Hollywood, and San Diego. The nullification of the indictments was requested by John McMahon, Assistant District Attorney, on grounds defendants have been tried at Los Angeles. In discussing the break-up of the ring, McMahon said: 'The main violators have gone to San Quentin, or are on their way, for ten to twenty-five years. There have been eleven convictions in Los Angeles, headquarters of the group. Twelve cases were dropped due to insufficient evidence.'

(Continued in Front Advertising Section, Page 23)

† The office addresses of the California State Board of Medical Examiners are printed in the roster on advertising page 6.

† This column strives to mirror the work and aims of colleagues who bore the brunt of Association work some twenty-five years ago. It is hoped that such presentation will be of interest to both old and new members.

CALIFORNIA BOARD OF MEDICAL EXAMINERS—INDEX

(Continued from December issue)

- Indictments, June 18, 1936, by San Francisco Grand Jury (abortion racket), July, 1936), p. 112
- Arden, Nedra, San Diego office nurse
- Beggs, James H., M.D., Oakland
- Byrne, William A., Los Angeles, former investigator for Medical Board
- Bole, Beatrice, Long Beach, etc., solicitor
- Cole, Grace, Long Beach, nurse
- Creeth, John, Los Angeles, Medical Acceptance Corporation
- de Gaston, Paul R., Los Angeles, layman participant
- Follet, Josephine, Hollywood, nurse
- Giubbini, L. J., D.C., San Jose
- Hable, Leola, San Francisco, office nurse
- Hanson, Ruth, Oakland, office nurse
- Houston, Harry L., M.D.
- Korf, Gladys, Los Angeles, office nurse
- McCarthy, Bessie, Los Angeles, rest home operator
- McEwen, Zora, Los Angeles, nurse
- Miner, Laura, San Diego, office manager
- Pattee, E. T., M.D., formerly of Los Angeles (license revoked)
- Pelegrini, Violette, San Jose, office nurse for Giubbini
- Powers, William Norman, M.D., Long Beach (license revoked)
- Perry, J. C., San Francisco, Medical Acceptance Corporation
- Raithel, Marvin, San Jose, drug clerk and solicitor
- Rankin, Reginald L., Los Angeles and San Francisco alleged promoter of the racket
- Rankin, Violet, wife of above
- Ross, Jesse C., M.D., San Francisco
- Shinn, J. O., Los Angeles and San Francisco, Medical Acceptance Corporation
- Smith, F. B., M.D., San Francisco and Oregon
- St. John, Valentine, M.D., Los Angeles
- Warner, Violet, Oakland, office nurse
- Watts, George E., M.D., Los Angeles, chief surgeon
- Wilson, Lillian, Oakland, office nurse
- Wilson, Mary, Oakland, office nurse

EVOLUTION of the VACOLITER

Baxter's Dextrose and Saline Solutions are Accepted by the Council on Pharmacy and Chemistry of the American Medical Association

The Baxter Vacoliter is the progressive result of designing and creating a score or more experimental dispensing containers for intravenous solutions.

Years and years before you heard about commercial ready-to-use solutions, Baxter engineers were busy creating . . . testing . . . discarding . . . to the end that the ultimate Baxter dispensing container should leave nothing more to be desired.

The result of this research is the Vacoliter, unique dispensing container that has won the Approval of the American College of Surgeons.

That you may be certain to get the advantages of the Vacoliter . . . that you may never be denied these advantages because of the existence of containers of similar appearance . . . the Vacoliter is fully patented.

The name "Vacoliter" molded in the glass on the 500cc, 1000cc and 2000cc Vacoliter protects you against substitutions. Look for the name "Vacoliter". Be certain you get the Vacoliter.

THEY are representatives of the General Electric X-Ray Corporation in your vicinity. They live here, work here — always within call when you need their help.

Time was when dealers and agents sold and serviced G-E equipment, theoretically assumed full responsibility for it. But to you, that was not always satisfactory. You didn't want responsibility divided between agent and manufacturer. We wanted to know, beyond question, that your equipment was performing properly, that you were given satisfactory service, and that adequate facilities were easily accessible to you.

The answer was the establishment of direct factory branches, and the selection and training of a large group of men who could be, to your satisfaction, the General Electric X-Ray Corporation in your vicinity. They were carefully selected, painstakingly trained to be able to help you in a highly specialized field. They *know* G-E x-ray and electro-medical equipment, and they can help you select the proper type and assist you in getting from it the ultimate in direct benefits.

If you don't already know the G-E man in your locality, we hope you'll get acquainted. He'll prove to be a worthy friend.

Rates, Information and Booklet on Request

Food and Drug Penalties Cover Variety of Offenses.
Fines imposed in cases recently brought under the Federal Food and Drugs Act ranged from \$1 and \$2 up to \$300 and \$500, the Food and Drug Administration reports. The total of fines assessed was \$2,563. . . .

These terminations were entered in cases involving medicinal preparations: Chicago Drug Sales Company, Chicago, Illinois, six seriously misbranded and adulterated patent medicines obtained principally through "salvage" operations, fine, \$25; John W. White, proprietor of White Herb Manufacturing and Remedy Company, Bessemer, Alabama, "White's Herb Tonic Compound," consisting of plant extracts in water and less than one-tenth of one per cent alcohol, offered for the treatment of stomach complaints, liver and kidney ailments, and indigestion, fine, \$300, six months' jail sentence suspended and defendant placed on probation for five years; Poloris Company, Inc., New York, N. Y., "Poloris Dental Poultice," containing belladonna leaves, hops, aconite, sassafras, and acacia, for the treatment of toothache, abscess, swelling or inflammation of the gums, gingivitis, and trench mouth, fine, \$125; Holford Company, Minneapolis, Minnesota, "Holford's Famous Inhaler," containing lavender flowers, mustard seed and oil of mustard, offered for the treatment of catarrh, headaches, asthma, hay fever, sinus trouble, cold in the lungs, sore throat, constant coughing, tonsillitis, toothaches, neuralgia, and fainting spells, fine, \$100; Erie Drug Company, Erie, Pennsylvania, an imitation vanilla flavor not labeled to show its imitation character, a "germ killer" found to be not germicidal when used as directed, and ten patent medicines variously represented as treatments for coughs, catarrh, croup, ulcers, skin diseases, rheumatism, cramps, backache, blood, liver, kidney and bladder disorders, erysipelas, dyspepsia, neuralgia, diabetes, grippe, hysteria, pneumonia, whooping cough, eczema, and pleurisy, fine, \$50 and costs; Timlake Products, Inc. (Henry F. J. Lake, President), Des Moines, Iowa, "Blu-V-Spray" and "Germite Wormer," fraudulently offered for the treatment of infectious diseases and worms in poultry, fine,

\$75 and costs; and Certified Laboratory Products, Ltd., San Francisco, impure nitrous oxide (laughing gas), fine, \$20. . . .

A survey of absorbent cotton, gauze bandages and similar products, generally represented to the purchaser as "sterile," has shown that many of these items are not free from bacteria, the Food and Drug Administration reports. Seizures were effected during the month of the following goods, on charges of interstility: 1,500 packages of absorbent cotton, 2,880 packages of gauze bandage, 5,000 gauze pads, and 35 first-aid kits containing absorbent cotton and gauze bandages. One lot of glucose-calcium ampoules, unsterile and low in calcium, was also seized.

Medicinals seized during October included 240 gallons of substandard cod-liver oil; 900 pounds of "De-Raef Milk Mineral Salts," consisting, despite the name, of 90 per cent corn sugar with small quantities of salt, magnesium and calcium compounds, and rennet; "Antiseptol," a mixture of boric acid, zinc sulphate and menthol, represented as antiseptic although having no antiseptic effect when used as directed, offered for the treatment of women's ailments; "Bell's Veterinary Medical Wonder," containing 63 per cent alcohol (the label stated 40 per cent alcohol), and plant drugs including alkaloids and resins, and flavoring, offered for colic, coughs, chills, refusal to eat, uneasiness, nervousness, exhaustion, abdominal pains, bloating, staggers, pleurisy, bronchitis, distemper, azoturia, garget, catarrh, and other ailments of horses, cattle, sheep, hogs, dogs, and poultry; "Kayan," containing phenolphthalein 1.2 grains per teaspoonful, gum, sugar, and starch, represented as the "granulated powder from the sap of an Asiatic tree," and although the product was itself only a cathartic and purgative, its label carried these statements: "pills, cathartics, and purgatives do more harm than good," "remarkable discovery," "new hope and health for millions," and "sweeps the poisons out of the intestines like a new broom cleans a room"; "Lane's Pills," containing calomel, a plant laxative, sugar, ferrous carbonate, and strychnin, for liver

troubles, headaches, indigestion, dizziness; "Lane's Tea—the Family Medicine," a mixture of crude drugs, insect-infested, offered for faulty elimination; "Nash's Carbolic Salve," consisting of petrolatum, carbolic acid, camphor, resin, and boric acid, whereas carbolic salve should contain only carbolic acid, yellow wax, and petrolatum, not antiseptic as claimed, and offered for the treatment of cuts, salt rheum, tetter, eczema, fever, sores, boils, felons, and pimples; "Nash's Pain-Go," kerosene, and volatile oils, including oil of turpentine and oil of sassafras, falsely represented as antiseptic, for pains, rheumatism, toothache, bunions, headache, lumbago, sore throat, stiff joints, and sore feet; "Nox-a-Boil," pills containing iron, calcium, and magnesium carbonates, phosphates, sulphates and chlorids, talc, sugar, starch, and fat, for boils, pimples, carbuncles, tonsillitis, sore throat, canker sores, discharging ears, infected wounds, septic infections, sprains, bruises, ulcerated teeth, abscesses, and inflammation; "Runner's Combined Eczema Lotion and Remedy for the Skin and Scalp," consisting of glycerin, water, boric acid, and small amounts of salicylic acid, wintergreen, and carbolic acid, for eczema, barber's itch, ringworm, tetter, salt rheum, pimples, ivy and oak poisoning, to allay itching and reduce inflammation; and "Seedol Kelpamalt Tablets," consisting of kelp (a sea weed), cocoa, sugar, salt, and saccharin, but no malt diastase although its presence was indicated by the label, and accompanied by a bookful of unsubstantiable claims of benefit in mineral and vitamin deficiencies, weight control, appetite improvement, constipation, and other conditions.

Modified United States Regulation on Dog and Cat Food in Effect.—Recent developments in the commercial preparation of dog food, cat food, and similar products have caused the Bureau of Animal Industry, United States Department of Agriculture, to modify its regulations pertaining to these products. Designated as Amendment 10 to B. A. I. Order 211, the new requirements provide for the withdrawal of the familiar meat-inspection stamp from containers of dog food and similar products. The new regulation provides, however, that containers of such products may bear the statement, "The meat or meat by-product ingredient of this article has been examined and passed under federal supervision. This article has been prepared in an establishment operating under federal meat inspection."

**For Acidity and Allied
Conditions, we suggest
ADAMS SPRINGS
MINERAL WATER**

● **MANY** physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and manganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm,

the kidney output is greatly increased, and there is marked drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

A Natural Mineral Water**SHOWING MAIN CONSTITUENTS***By PROF. SYDNEY A. TIBBETTS, Berkeley*

The regulation, now in effect, also provides that the regular meat-inspection legend as used on food intended for human consumption may not be used on food designated as being intended for dogs, cats, foxes, and similar

(Continued on page 44)

DIGITOL

WHEN the physician prescribes a digitalis preparation, he expects to receive a uniform and thoroughly dependable product. Our laboratories early recognized the necessity for a uniform tincture of digitalis and, sensing the direction of scientific medicine in the greater accuracy of dosage, applied physiological assay methods in the standardization of Digitol as early as 1901.

Today, each lot of Digitol is physiologically standardized by the "one-

hour frog method" official in the U. S. P. XI. The date of this test appears on the label of each bottle.

Digitol is a fat-free tincture; it makes a more slightly mixture with water on administration. Its elegant appearance, absence of precipitation, accurate standardization and dependable activity are advantages which have been maintained. Digitol is marketed only in one-ounce sealed bottles supplied with a dropper for ease of administration.

An Accepted, Highly Effective Milk Modifier... at an Approximate Cost of

2¢

PER DAY

ON THE basis of tested and approved feeding schedules averaged for babies up to the age of nine months, one tablespoon of Karo would be used with about 6 fluid ounces of milk. On this basis, a one and one-half pound tin of Karo (which sells in grocery stores for about 12c) will furnish the necessary amounts of easily assimilated carbohydrates, dextrin, maltose and dextrose,

for 6 quarts of whole milk. Probably no other infant food of equal acceptance is available at such low cost as Karo.

Mothers, generally, will appreciate their doctors' suggestion of Karo as an effective, economical milk modifier.

Karo is accepted by the Council on Foods of the American Medical Association.

★ Infant feeding practice is primarily the concern of the physician, therefore, Karo, for infant feeding, is advertised to the Medical Profession exclusively.

(Continued from Page 41)

animals. Thus, the inspection legend, "U. S. Inspected and Passed by the Department of Agriculture," is reserved exclusively for foods intended for human consumption.

The essential purpose of the new amendment is to inform the public that the meat ingredient has been inspected and passed, but that inspection has not included various other ingredients with which the meat has been combined.

The amendment further provides that when dog food or like articles are prepared in a part of a federally inspected establishment, its sanitation shall receive the same supervision as other parts of the establishment.

Details concerning the bureau's supervision of dog food and like products and their proper labeling are set forth in an official notice to supervising inspectors and proprietors and operators of establishments where such products are prepared. The Department of Agriculture also has arranged to receive reports to be used for statistical purposes relating to the commercial output of this class of product.

Teachers: Are These Suggestions Worth While?—

A large percentage of teachers are victims of nervous disorders, tuberculosis, gastro-intestinal disorders, and other conditions. It is of greatest importance that educational authorities guard the health of the teachers, thus indirectly affecting the health of the children.

1. If you live and work within your mental and physical margin of safety, you will live longer.
2. If you take regular periods of rest when you are tired, your efficiency will be greater.
3. If you exercise regularly, you will stimulate your metabolism and the function of all your vital organs.
4. If you establish correct eating habits, avoiding irregularity of meals and "food fads," you will prevent illness.
5. If you maintain good elimination, you will get rid of harmful toxins and ward off serious ailments.

6. If you stay at home in bed when you have an acute infection, you will save your own health and avoid spreading disease.

7. If you take showers, tempered to your individual reaction, every morning instead of indulging in too many hot baths, you will increase your resistance.

8. Reflect in your actions how happy you are to be well and not crippled or suffering pain from chronic disease; for children's health and happiness depend a great deal on your attitude toward them and toward life in general.

9. Your pupils imitate *you* and if you are kind, generous, courageous, and upright, you may do more good in building up the children's characters than many lectures would do.

10. A teacher, by her behavior, may become the great ideal toward which her children are striving, influencing their entire lives and characters.

11. Visit your family doctor once a year for a general check-up. You check your car for defects, why not check your own machinery, which is far more important than your automobile. A check-up once a year may prevent a very serious chronic disease, may prevent years of suffering and dependence.—Sven Lokrantz, M. D. (Los Angeles City School District, Health Section).

So long as the interests of the public health are guarded and advanced, the interests of the medical profession will follow. In other words, the interests of the health of our citizens and the interests of the medical professions are inseparable.—Ralph M. Carter, M. D., President, State Medical Society of Wisconsin.

Yet all experience is an arch where through
Gleams that untraveled world whose margin fades
Forever and forever when I move.

—Alfred Tennyson

WE do not claim that Poland Water is a cure for any disease: We offer it as a water extremely pure—chemically and bacteriologically—that is neutral and that may be an addition to your armamentarium.

For Doctors who are interested in Allergy Diets

... here's a helpful diet and recipe booklet

With this booklet your patients can more accurately follow the wheat, egg or milk-free diet you prescribe. Planned with the aid of leading allergists and dietitians, it provides complete lists of allowed and forbidden foods. Also practical advice to help patients guard against such common food anomalies as the wheat flour in rye bread, the egg in many baking powders, the milk in which many margarines are churned.

These books are for professional use and distribution only. None are ever distributed to the laity. In examining the booklet, you will find that Ry-Krisp is frequently used in the approved recipes. That's because these wafers—made of flaked whole rye, salt and water—are perfectly safe. Besides, because of their brittle-crispness and unique flavor patients gladly eat Ry-Krisp as bread at every meal. For free samples and Allergy Booklets, use the coupon below.

RESULTS—SIMPLICITY

BREAST MILK

from the Normal
Mother is the
IDEAL FOOD
for the
Human Infant

S. M. A. is a food for infants — derived from tuberculin tested cows' milk, the fat of which is replaced by animal and vegetable fats including biologically tested cod liver oil; with the addition of milk sugar and potassium chloride; altogether forming an antirachitic food. When diluted according to directions, it is *essentially similar to human milk* in percentages of protein, fat, carbohydrates and ash, in chemical constants of the fat and in physical properties.

That Is Why S.M.A.

is made to resemble
BREAST MILK

in percentages of carbohydrate, protein, fat and total salts (ash) content, and why even the chemical and physical constants of the fat in S. M. A. are like those of breast milk fat.

S. M. A. CORPORATION . . . CLEVELAND, OHIO

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

ROBERT A. PEERS, M. D., *Medical Director*
Colfax, California

Rx To be taken
twice a day at
Mealtime!

OUTSTANDING physicians today recommend baby foods with the same care they exercise in prescribing medicines. That's only natural. Strained foods and drugs share a common responsibility in infant welfare.

Equally understandable is the fact that more and more doctors are prescribing Heinz Strained Foods exclusively.

For one thing, each tin of Heinz Strained Foods bears the Seal of Acceptance of the American Medical Association's Council on Foods. And like the great names in phar-

maceutics, Heinz Strained Foods carry a distinguished quality reputation—the heritage of almost 70 years unceasing effort to produce the world's finest pure food products.

To millions, this hidden value is expressed in the famous "57" Seal of Quality. Only Heinz Strained Foods possess it.

That is why we say, "Specify Heinz Strained Foods—for infants and other soft diet cases—twice a day at mealtime. You can be sure they will meet the most exacting demands for high nutrient content, easy digestibility and appetizing flavor."

HEINZ STRAINED FOODS

57

11 KINDS—1. Strained Vegetable Soup. 2. Peas. 3. Green Beans. 4. Spinach. 5. Carrots. 6. Beets. 7. Prunes. 8. Cereal. 9. Tomatoes. 10. Apricots and Apple Sauce. 11. Mixed Greens.

*"Can chronic
arthritis be
treated with
vaccine?"*

CUTTER Laboratories
BERKELEY, CALIF.

MANY OF THE favorable reports of recent years on the treatment of chronic arthritis with vaccine have undoubtedly been over enthusiastic and uncritical. It remains a fact, however, that a number of competent clinicians and investigators find definite value in such preparations in selected cases; although opinion is divided both as to the type of case and the type of vaccine offering the most promise.

Sherwood's work with various types of vaccine intravenously is particularly encouraging, in-as-much as his results have averaged better than other series reported, while at the same time his cases have been well controlled.

For a review of the literature send the coupon.

Cutter Laboratories, Berkeley, California.

Please mail me a copy of your review of the literature on the treatment of chronic arthritis with vaccine.

Limited Facilities for Part-Pay Treatment

VISION

Fulfilled

IN 11 SHORT YEARS

Founded by Walter Jenkel and Forrest Davidson 11 years ago, the Jenkel-Davidson Optical Company now presents to the Medical Profession, America's outstanding Optical Prescription Headquarters, at Union Square, San Francisco.

"Professional duty and professional honor" . . . five words tell the story of the Jenkel-Davidson Organization. With facilities immeasurably increased, its aims remain set to the same high standard of service to the Ophthalmologist. The name Jenkel-Davidson Optical Company is recognized as full guarantee of skill, knowledge and honor in the manufacture and dispensing of eye glasses for patients of the medical profession.

Serving the Otologist as well, the new main store contains a complete Hearing Aids Department. Here again is found the same protection of interests. Audiometric readings are not made without a written order from the doctor.

It is with pride, with hope, with confidence that Walter Jenkel and Forrest Davidson await your visit to their new headquarters.

February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our
laboratories, we have been able to render
Emmenin entirely free from disagreeable
taste and odor. This has been accomplished
without loss of therapeutic activity, and the
potency is ensured by carefully controlled
biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and stand-
ardized under direct control of the Depart-
ment of Biochemistry, McGill University.

Manufactured by

Ayerst, McKenna & Harrison

Meeting, *Sunday Evening once a month.*

Ventura County Medical Society
President, F. R. Hendricks, 885 East Main Street, Ventura.
Secretary, A. A. Morrison, 625 Main Street, Santa Paula.
Meeting, *Second Tuesday, Ventura County Country Club.*

Yolo-Colusa-Glenn County Medical Society
President, Stanley E. Coffey, 239 Fourth Street, Orland.
Secretary, Ray E. Nichols, Woodland.
Meeting, *First Tuesday.*

Yuba-Sutter County Medical Society
President, Stanley R. Parkinson, 434 Fourth Street, Marysville.
Secretary, Fred W. Didier, Wheatland.
Meeting, *Second Tuesday.*

A PALATABLE COD LIVER OIL EMULSION

AT LOW COST TO THE PATIENT

MALTINE WITH COD LIVER OIL* is also guaranteed to contain vitamins A, B, D and G. In addition it contains other nutritive factors not found in plain cod liver oil. Laboratory tests on animals indicate that the vitamin A efficacy of cod liver oil is enhanced *two-fold* when emulsified in Maltine as in **MALTINE WITH COD LIVER OIL**. **MALTINE WITH COD LIVER OIL** and Iron Iodide is also available, containing two grains of freshly prepared iron iodide per fluid ounce.

**Containing Maltine 70%, cod liver oil 30%.*

THE BEST TEST IS THE CLINICAL RESPONSE

Here is an opportunity to prove that endotoxic infections respond rapidly when treated with

EDWENIL

the polyvalent, protein-free, antibacterial agent. The salient points are these:

(1) The promptness of the response; the defenses are aroused immediately, resulting in a "shower of antibodies."

(2) There are no detrimental "reactions" nor unpleasant anaphylactic phenomena.

Edwenil is indicated in all endotoxic bacterial invasions—**respiratory infections, such as pneumonia, influenza, and colds**; septic conditions, such as abscesses, boils, and carbuncles; acute specific fevers, such as whooping cough and measles.

Pneumonia should be typed!

ANTIPNEUMOCOCCIC RABBIT TYPING SERA *Lederle*

CLINICAL ASPECTS do not serve to distinguish the different types of pneumococcus infections.

Not infrequently a striking result in serum therapy has been observed in atypical pneumonia considered not pneumococcal before the type was determined.

The Neufeld method, for immediate pneumococcus typing directly from sputum, represents one of the most important advances in modern serum therapy. It is simple, accurate and permits of a diagnosis being made within a few minutes' time. The method may be employed by any physician once the technique involved is learned, or typing may be done through the aid of a nearby hospital or laboratory. Materials necessary for the test are: a microscope, slide cover slips, and

ANTIPNEUMOCOCCIC RABBIT TYPING SERA *Lederle* containing methylene blue, for Neufeld Reaction Test, ready for immediate use.

LEDERLE'S PNEUMONIA SERVICE INCLUDES

FOR DIAGNOSIS:

Rabbit Typing Sera, for Neufeld Reaction, for Types I to XXXII, supplied in the following packages:
0.5 cc. vial 5 capillary tubes

FOR TREATMENT:

Bivalent Types I and II as well as Monovalent Antipneumococcic Serum, supplied in the following packages:
10,000 units in syringe 20,000 units in syringe

CO-OPERATE WITH YOUR ADVERTISERS

CALIFORNIA AND WESTERN MEDICINE, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention CALIFORNIA AND WESTERN MEDICINE.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this JOURNAL to members and readers.

A SERVICE AGENCY—FOR READERS

THE JOURNAL of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely free to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail. Perhaps you want a certain kind of instrument which is not advertised in CALIFORNIA AND WESTERN MEDICINE, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. CALIFORNIA AND WESTERN MEDICINE and the A. M. A. Service Bureau desire to serve you.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE

(In affiliation with COOK COUNTY HOSPITAL)

Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses.

SURGERY—General Course One, Two, Three and Six Months; Two Weeks Intensive Course Surgical Technique (Operative Surgery with Practice); Clinical Courses.

GYNECOLOGY—Three Months Course; Intensive Two Weeks Course starting February 15, 1937.

OBSTETRICS—Informal Course; Special Courses.

FRACTURES AND TRAUMATIC SURGERY—Informal Practical Course; Ten Day Intensive Course starting February 15, 1937.

EAR, NOSE AND THROAT—Informal Course; Personal Courses; Intensive Two Weeks Course starting April 5, 1937.

OPHTHALMOLOGY—Intensive Two Weeks Course starting April 19, 1937.

UROLOGY—General Course Two Months; Intensive Course Two Weeks; Special Courses.

CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

GENERAL, INTENSIVE AND SPECIAL COURSES IN ALL BRANCHES OF MEDICINE AND SURGERY.

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 South Honore Street, Chicago, Ill.

ABDOMINAL SURGERY

The Continuous Course Is Now in Session

STUDENTS MAY ENTER AT ANY TIME

The following subjects will receive special attention:

Stomach and duodenum, colon and rectum, gall-bladder and bile ducts, small intestines.

The work will be given every Tuesday from 11 a.m. to 3 p.m. Those desiring to divide the work into two sessions may report on Tuesdays and Thursdays from 11 a.m. to 1 p.m. The fee is \$15 per month.

Applicants must be graduates of schools approved by the State Board of Medical Examiners

For descriptive circular and further information inquire of

Vision in College Students.—Obtaining a college education involves a definite strain on eyesight for many students, it was pointed out by Dr. Ruth E. Boynton of Minneapolis, in an address before the annual conference of the National Society for the Prevention of Blindness in Columbus, Ohio, recently. Doctor Boynton is associate professor of preventive medicine and public health at the University of Minnesota and director of the Students' Health Service for the University.

Reporting on a study of the changes in vision which took place among one thousand students during their four years at the University of Minnesota, Doctor Boynton said that about one in six of those entering college had seriously defective vision, but the percentage increased to about one in four by the time they were graduated. Most of these students were enrolled in the Medical School or the College of Education. She said that, upon entering the University, 52 per cent had normal vision, 18 per cent had serious defects in vision, and 30 per cent had slight defects in vision. At the time of graduation, however, eye examinations disclosed that 24 per cent had seriously defective vision.

Doctor Boynton observed that "students having the lowest visual acuity when entering the University had the most marked decrease in vision at the end of four years." She reported also that myopia, commonly known as nearsightedness, is apparently less of a handicap than either farsightedness or astigmatism, since a large percentage of nearsighted students were among those with the highest scholastic ranking.

"Stone walls do not a prison make
Nor iron bars a cage."

Winter is a jailer who shuts us all in from the fullest vitamin D value of sunlight. The baby becomes virtually a prisoner in several senses: First of all, meteorologic observations prove that winter sunshine in most sections of the country averages 10 to 50 per cent less than summer sunshine. Secondly, the quality of the available sunshine is inferior due to the shorter distance of the sun from the earth, altering the angle of the sun's rays. Again,

The Tulane University of Louisiana

Graduate School of Medicine

POSTGRADUATE instruction offered in all branches of medicine. Special courses are offered in certain subjects. Courses leading to a higher degree are also given.

For bulletin furnishing detailed information, apply to the . . .

DEAN

Graduate School of Medicine
1430 Tulane Avenue New Orleans, La.

the hour of the day has an important bearing: At 8:30 a. m. there is an average loss of over 31 per cent, and at 3:30 p. m. over 21 per cent.

Furthermore, at this season the mother is likely to bundle her baby to keep it warm, shutting out the sun from Baby's skin; and in turning the carriage away from the wind she may also turn the child's face away from the sun.

Moreover, as Dr. Alfred F. Hess has pointed out, "it has never been determined whether the skin of individuals varies in its content of ergosterol" (synthesized by the sun's rays into vitamin D) "or, again, whether this factor is equally distributed throughout the surface of the body."

While neither Mead's Oleum Percomorphum nor Mead's Cod Liver Oil Fortified With Percomorph Liver Oil constitutes a substitute for sunshine, they do offer an effective, controllable supplement, especially important because the only natural foodstuff that contains appreciable quantities of vitamin D is egg-yolk.

Ten Principles in Health Teaching.—1. We must teach the body as a whole rather than as a collection of anatomical and physiological systems.

2. We must attempt to create in the mind of the child a vast admiration for the body and its various processes.

3. We must bring out the point in every possible instance that health and disease are the results of adequate cause, and that there is nothing of the supernatural or adventitious in the various processes involved.

4. We must make the health program a happy one. Beauty, grace, strength, endurance, and efficiency must take the place of the opposite qualities as motivating agents.

5. We must make the subject interesting else it will be boring and soon forgotten.

6. We must teach living rather than the technique of living. Hygiene must throb with life; it must be vital and to the point so that it will meet the problems of life.

7. We must teach hygiene in relation to the procession of life that reaches back to the day of creation. The human species bears certain relations to heredity and environment which are essentially the same as those of other living things and are best understood by a study of lower forms.

8. We must teach, on the other hand, that the human species has also a higher destiny and that there are considerations of morals, esthetics, ethics, social relations and responsibilities, culture and civilization, which have no counterpart in the lives of lower forms.

9. We must teach health as a means to a higher end and not as an end in itself.

10. We must somehow make the child understand that life is adaptable—that life finds a way—that life grows and develops.—Thurman B. Rice, M.D., in *Indiana Health Bulletin*.

Man cannot degrade woman without himself falling into degradation; he cannot elevate her without at the same time elevating himself.—Alexander Walker.

**NUTRI-AD
ARTHROPHYLL**

(6)

A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » » »

NUTRI-AD—ARTHROPHYLL(6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL(6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

BOOK REVIEWS

Books received for review are placed in the Library of the California Medical Association, in its central office at San Francisco. Book reviews are written by the Association Secretary.

BOOKS RECEIVED

Synopsis of Anorectal Diseases. By Louis J. Hirschman, M. D., F. A. C. S., Former Vice-President, American Medical Association; Former Chairman, Section on Gastro-Enterology and Proctology, American Medical Association; Former President, American Proctologic Society; Professor of Proctology, Wayne University; Fellow (Honorary) Royal Society of Medicine, etc. Cloth. Pp. 288, with 174 text illustrations and six color plates. Price, \$3.50. St. Louis: The C. V. Mosby Company, 1937.

Physical Therapeutic Methods in Otolaryngology. By Abraham R. Hollender, M. D., F. A. C. S., Associate in Laryngology, Rhinology, and Otolaryngology, University of Illinois College of Medicine; Fellow of the American Academy of Ophthalmology and Otolaryngology. Cloth. Pp. 442, with 189 illustrations. Price, \$5. St. Louis: The C. V. Mosby Company, 1937.

The Management of Obstetric Difficulties. By Paul Titus, M. D., Obstetrician and Gynecologist to the St. Margaret Memorial Hospital, Pittsburgh; Consulting Obstetrician and Gynecologist to the Pittsburgh City Homes and Hospital, Mayview, and to the Homestead Hospital, Homestead, Pennsylvania; Secretary of the American Board of Obstetrics and Gynecology. Cloth. Pp. 879, with 314 illustrations, including four color plates. Price, \$8.50. St. Louis: The C. V. Mosby Company, 1937.

On Your Guard! The Prevention and Treatment of Sex Diseases. By Carl Warren, B. A., B. S., M. S. J., Advised and Assisted by Eminent Specializing Physicians. Foreword by M. J. Exner, M. D., Director of Educational Department and Consulting Physician of American Social Hygiene Association; Director of Sexual Education, International Committee, Y. M. C. A.; in Charge of Social Hygiene Education for United States Army during World War. Frontispiece and illustrations by C. D. Batchelor. Cloth. Pp. 160. Price, \$1. New York: Emerson Books, Inc., 1937.

Proceedings of the Thirtieth Annual Convention of the Association of Life Insurance Presidents. Held in the Waldorf-Astoria, New York City, December 3 and 4, 1936. Paper. Pp. 251. Printed in the United States.

BOOK REVIEWS

The Management of Obstetric Difficulties. By Paul Titus, M. D., Pittsburgh. Pp. 879, with 314 illustrations. Price, \$8.50. C. V. Mosby Company.

Obstetrical emergencies must be met promptly because of their nature and because delay or expectancy increases mortality and morbidity. Titus has written this text on obstetrical difficulties and emergencies for the general practitioner who accepts obstetrical cases. Specialists will find it to be an addition to their libraries.

Study of this text should enable one to early recognize emergencies and to initiate proper procedures. Next, it

BOOK REVIEWS

(Continued from Preceding Page)

presented his own experience and advice. All in all, this is a most worth while contribution, meriting a place on the desk of every general practitioner.

Physical Therapeutic Methods in Otolaryngology. By Abraham R. Hollender, M. D., University of Illinois. Pp. 442, with 189 illustrations. Price, \$5. St. Louis: C. V. Mosby Company.

A review and clinical evaluation of physical therapeutic methods. The main text is devoted to clinical problems. The author describes indications and technique. On the whole, it is a quite satisfactory text for the student and beginner. It is sound in the groundwork that it lays and should guide one to seek extended clinical practical experience.

Synopsis of Anorectal Disease. By Louis J. Hirschman, M. D., Detroit. Pp. 278, with 174 illustrations. Price, \$3.50. St. Louis: C. V. Mosby Company.

After having written an accredited textbook on the same subject, it is difficult to find any reason as to why Hirschman should desire to put out this synopsis. It is a synopsis only, with many important details omitted. Good as far as it goes, but lack of completeness prohibits approval and recommendation. Detailed review space is not warranted.

On Your Guard: The Prevention and Treatment of Sex Diseases. By Carl Warren, B. A., B. S., M. S. J. Pp. 160. Price, \$1. New York: Emerson Bros., Inc.

An informative, reliable book on venereal infections, addressed to the lay public. Can be recommended to those seeking dependable information.

It is a great cleverness to know how to conceal our cleverness.—Rochefoucauld.

Your Patients Will Be Grateful

AT the A. M. A. Convention last June we recorded interviews with over 4,000 physicians. In a surprisingly large percentage of these interviews the doctor produced a Benzedrine Inhaler from his pocket and said, in effect: "I wouldn't be without it . . ."

So emphatic were these favorable opinions that we cannot but feel that Benzedrine Inhaler has won the good will of the medical profession to a surprising degree. The busy physician seems to be genuinely grateful for its immediate effectiveness, its convenience—and the fact that it is handy for use at *any* time and in *any* place.

And your patients will be equally grateful when you suggest Benzedrine Inhaler as a practical first aid measure to be used at the first sign of nasal congestion—in head colds, hay fever or sinusitis.

Each tube is packed with benzyl methyl carbinamine, .325 gm.; oil of lavender, .097 gm.; and menthol, .032 gm. "Benzedrine" is the registered trade mark for Smith, Kline & French Laboratories' brand of benzyl methyl carbinamine.

BENZEDRINE INHALER

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.

In Sinusitis

...BETWEEN OFFICE TREATMENTS

In acute and chronic sinusitis, the maintenance of maximal aeration and adequate drainage *between office treatments* often presents a problem difficult to physician and patient alike.

The use of liquid vasoconstrictors applied by spray or dropper during social activities or business is accompanied by obvious disadvantages. Benzedrine Inhaler, however, can be used inconspicuously at any time and in any place. Its convenience of appli-

cation goes far toward insuring the comfort and co-operation of your patients.

Being volatile, Benzedrine penetrates to areas not readily accessible to liquid inhalants, promptly reducing engorgement wherever it exists in the rhinological tract. And, by re-establishing drainage of the accessory sinuses, it may often help to prevent acute attacks from becoming chronic.

Prolonged use of the inhaler does not tend to produce tolerance or atony.

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.—EST. 1841

Original Articles.—The *Journal* is always glad to receive original articles, whether they have been read before the Society or not. Short reports of clinical cases of general interest are particularly desirable. Illustrations, when they are really necessary to elucidate or really add to the text, will be made at our expense, provided the author furnishes clear and satisfactory drawings or photographs. *Manuscript should never be rolled.* It should be sent flat, between boards, or folded. It must be typewritten to receive consideration. Authors should remember that the compositor, or typesetter, puts into type exactly what he sees before him on the manuscript, unless it is otherwise marked. Look at your manuscript with this fact in mind and picture to yourself what it will look like when put into type exactly as you have written it. It is a very common thing for an author to abbreviate certain words in order to save the trouble of writing them out. They are simple and obvious abbreviations to him, but they are meaningless to the typesetter. Also, they would not infrequently be almost meaningless to any other reader, to say nothing of the fact that a scientific communication is supposed, so far as we are concerned, to be a statement of things in the English Language and not a guessing contest or a puzzle. "Ant. sup." may mean anterior superior to the author, but we would hate to say what it might look to the compositor! Not infrequently otherwise valuable manuscripts have to be returned for this reason. Furthermore, *please* try and spell proper names correctly every time they are used. To find a reference to "Dr. Smith" on one page and to the same man as "Smythe" on another is, to say the least, somewhat confusing; when repeated, with further variations, it has been known to cause violent profanity. Charts, and especially tables when they are at all extended, complex or bulky, are very expensive things to reproduce, and ninety-nine times in a hundred are not half so necessary or important as the author thinks they are. Of course, it is always the editor's fault if an article submitted does not receive publication. No author has ever been known who would admit the slightest reason for withholding publication except the cantankerousness or personal bias of the editor. That seems to be human nature. An author will write: "The matter is so well

Is purer Nitrous Oxide desirable?

Many anesthetists think so—and use Stuart Hi-Pure (cylinder on left) because it is 99+% pure; so far as we know, the *only* Nitrous Oxide of such purity. Cylinder on right is Stuart Nitrous Oxide of ordinary purity (over 95% by volume, as required by U.S.P. specifications). Notice the effect of free nitrogen on purity as it is passed out with Nitrous Oxide during use.

PORTLAND

TACOMA

known to you all that it seems hardly necessary to mention it"—and then proceed, for the next few pages, to write out what is "so well known to you all"; and then if this portion of his article is "cut out" he is quite hurt.

These are just a few suggestions with nothing personal about them and no special articles or authors in mind (that is not entirely true). If you will read them over and think about them it will be a great help to (1) yourself, (2) the editor, and (3) the compositor.

1 1 1

Medical Defense.—The following circular letter was prepared by the attorney for the State Society in July, 1909, and a copy was sent to every member of the Society. It was published at least twice in the *Journal*, but it seems wise to publish it again. To the statements made therein it is only necessary to add that the plan has proved to be a complete success. It is no longer an experiment, but

TWENTY-FIVE YEARS AGO

(Continued from Preceding Page)

an everyday working part of the machinery of the State Society. Do not waste time wondering "if it will work out"; it has worked out; it is a perfect success. . . .

From an article on "Medical Organizations and Conservation of the Public Health"—President's Address at the Annual Meeting of the Los Angeles County Medical Association, December 15, 1911. By W. Jarvis Barlow, M.D., Los Angeles.—Conscious of a high trust and mindful of greater happiness, the men and women of the medical profession have ever stood for the betterment of human conditions. They have accomplished humanitarian work through personal efforts, unselfish actions, overwork, with or without remuneration, visiting the rich and the poor, by constructive work for the relief of suffering through hospitals, dispensaries, health camps, settlements and the several relief organizations in one way or another, to make life easier, healthier and better, and to help a universal need—the prevention of disease. As individuals they stand well and are respected by their neighbors, friends, and the community; but collectively or as an organized body they seem to hold, at the present time, a different and somewhat unpopular position. Honor and appreciation of altruistic endeavor are rarely accorded and should not be expected by those who act from the highest motives. . . .

Proceedings of the San Francisco County Medical Society—Address of Doctor Ophüls, President—Annual Meeting of San Francisco County Medical Society, December 12, 1911.—At the beginning of my presidential address it is my pleasant duty to express my great and most sincere appreciation to the Board of Directors and to the members of the San Francisco County Medical So-

ciety for electing me to fill this most important office in the Society. I shall always look back upon this year with the greatest pleasure in view of the most cordial and effective support given me by the Society at large, more especially by those who undertook the often arduous duties on the different standing and special committees and by the individual members of the Board of Directors, without which splendid support it would have been impossible to accomplish anything. . . .

The question of renting meeting and office rooms from the trustees of Leland Stanford, Jr., University and of our placing our library in the same building, was fully discussed by a special committee, consisting of Drs. W. W. Kerr, Dudley Tait, P. M. Jones, R. L. Porter, and Charles G. Levison. A statement in regard to the matter was submitted to the members of the Society. A large majority of those who answered expressed themselves in favor of the proposal. Replies were received from about two-thirds of the membership. In spite of this expression of opinion, the Board of Directors decided to lay the matter on the table, largely because there seemed to be some fear that the Society was unable to meet the requirements of the contract which was proposed, financially. I believe that the question is not solved finally. The Society needs better accommodations for its meetings, its offices, and for the library. The placing of the two libraries in one building and the creation of a medical center in San Francisco would be of inestimable benefit to the profession. So far as I can see, the necessities of the Society could not be met by any other scheme on more advantageous terms, and I personally am still strongly of the opinion that at some future date the logic of facts will convince even the most conscientious objector, and no doubt an arrangement can then be made which at the same time would satisfy any demands which the Society can justly make and give the profession what it needs—a large collection of medical literature under one roof, administered independently, if you will, to common advantage.

(Continued on Page 20)

CONSERVATION OF ESSENTIAL ELEMENTS IN PROTECTIVE FOODS

II. THE VITAMINS

● Refinement of vitamin assay methods has made practical many quantitative studies which had hitherto been impossible. Employment of these methods has yielded evidence which indicates that many factors may influence the vitamin content of foods which come to the table; in particular, the fruits and vegetables. Variety, maturity, time and temperature of storage after harvesting, and method of preparation, all have been found to affect the ultimate vitamin content of common foods. Several examples of the extent to which certain of these factors operate might well be given.

It has been shown that spinach slowly loses its vitamin C potency even in low temperature storage; at room temperature, one-half of the vitamin C is lost in three days; practically all antiscorbutic potency disappears in seven days (1).

Another report indicates a loss in vitamin C of 78 per cent in spinach stored two days at room temperature and 80 per cent loss in asparagus tips during four days' storage (2).

The vitamin C content of apples is markedly reduced during cold storage: 20 per cent in 4 to 6 months and about 40 per cent in 8 to 10 months (3).

Vitamin A in apples is, however, subject to less destruction than vitamin C during prolonged storage (4).

Prolonged cold storage of pears may result in a loss in the vitamin A and vitamin C content of nearly 50 per cent (5).

Further, solution losses which may occur during cooking vary with the individual product and with the method used in cooking. From 40 to 48 per cent of vitamin C may be lost to the water in which peas are cooked (6).

Vitamin C losses in 12 different vegetables have been reported to vary from 12 per cent in asparagus to 80 per cent in white onions (7).

These data demonstrate the seriousness of solution losses of vitamin C. It is considered probable that other water soluble vitamins are affected in a similar way.

Thus, by the time fruits and vegetables spend some days in transit or storage before reaching the kitchen and are cooked by the usual home method, much of the original vitamin content may have been lost. Little can be done to prevent storage losses when fresh fruits and vegetables are not available from the home garden, but solution losses may in part be overcome by using the cooking water.

Fortunately, in the commercial canning procedure, products are harvested at the optimum stage of maturity and canned immediately, using only a limited quantity of water which is retained in the can. As a result, storage losses of the vitamins are reduced (8), and solution losses may be eliminated by the use of the liquid in which the food is canned.

This is the twenty-first in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Council on Foods of the American Medical Association.

TWENTY-FIVE YEARS AGO

(Continued from Page 18)

I also wish to call the attention of the Society to the existence of a considerable fund for the benefit of its own library. We have in our possession a capital of \$8,000 originally given for relief purposes, which on July 14, 1913, when it will have increased to \$10,000, becomes available for library purposes under the direction of our Board of Directors. . . .

Report of the San Francisco Medical Milk Commission. It is with much pleasure that after five years' connection with the Certified Milk Commission of this Society, I am now able to give you the present report of its progress.

The affairs of the Commission were never more flourishing. Five years ago when we met to organize the Commission, we had the promise of 190 subscribers, each of whom agreed to take a quart of certified milk daily, provided someone could be found who would, on this slender encouragement, be willing to undertake its production. . . .

Report of the Committee on Legislation.—At the last session of the State Legislature various medical bills of all kinds and sorts were introduced in both houses. Bills defining the practice of medicine; providing fines for illegal practitioners; for the appointment of a board on mechanotherapy, and other of even lesser import. These serially met defeat. Realizing that the appointment of any board by the Governor would always appeal to the political mind, Senator Hurd introduced a bill (Senate Bill 875), providing for the appointment of a board of medical examiners by the Governor; also, providing for the issuing of three forms of certificates—one for the practice of medicine and surgery; one for the practice of osteopathy; one for the practice of any other form of medicine—also legalizing the practice of an Oakland quack of thirty-five years' standing in deception. Although we had the best

reason to believe that this bill would never become a law, even though passed by both houses, nevertheless, contrary to our expectations, the Governor signed the Hurd bill and it is now a law of the State. However, the Governor has never taken advantage of the opportunity afforded him to appoint a new board, preferring to allow the board selected by the respective medical societies to continue in office. The law as it now stands is not in accord with the opinion of the profession, and a determined effort must be made at the next regular session of the State Legislature to have it so amended that it will be once more in harmony with the best interests of the public.

Respectfully submitted,

F. B. CARPENTER,
Chairman, Committee on Legislation.

From an article on "Some Remarks on So-Called Automobile Fractures" by W. H. Winterberg, M. D., San Francisco.—The fact that there is much misconception among both the laity and physicians about just what a so-called automobile fracture is and how it is caused, is perhaps excuse enough for bringing before you a subject which has been well worked out and cases of which are becoming less yearly.

When I use the term "automobile fractures"—they are also called chauffeur's fracture, automobile crank fractures—I mean cases of fracture of the lower and usually outer end of the radius caused by the sudden and violent reversal of the starting crank of an automobile—the so-called "kick-back."

Lane Lectures, 1912.—The thirtieth annual course of Lane lectures will be delivered in Lane Hall, Cooper Medical College, beginning Friday evening, January 12, at eight o'clock, and continuing every alternate Friday evening thereafter, until the lectures are given. These lectures are free and no ticket of admission is required. . . .

"A supply in the bag; a supply in the office —*always!*"

No physician knows, when he starts his day, what critical situations will confront him. Because this product is essentially an emergency remedy, many physicians make a practice of keeping at hand at all times a supply of Adrenalin Chloride Solution 1:1000 (the Parke-Davis brand of Solution of Epinephrine Hydrochloride U.S.P.).

Medical men and women

throughout the world have been relying on the original Parke-Davis product every hour of the day and night for thirty-five years; and the resources and personnel of the Parke, Davis & Co. laboratories of today are pledged to maintain its unvarying dependability. A request will bring the booklet "Adrenalin in Medicine" by return mail.

BOARD OF MEDICAL EXAMINERS

(Continued from Page 20)

Sheriff Ullery in 1931." (Yuba City *Independent-Farmer*, January 1, 1937.) Roy L. Martin was prominently featured in the 1930 annual report of the Board of Medical Examiners, classified among the "Eyesight Swindlers." The United States post-office inspectors are rounding them up throughout the United States.

Another eyesight swindler, named Louis Levy, was reported arrested in Los Angeles December 2, 1936, by post-office inspectors.

"Two women, arrested in a raid on a house at 947 Neptune Street, Wilmington, were booked at University police station last night on a suspicion of performing illegal operations. The women gave their names as Miss Elsie Spencer, twenty-six, and Mrs. Lillian Foster, twenty-seven, and said they were sisters. Acting on information furnished by a 16-year-old girl, Detective Lieutenant W. J. Sims and Policewoman Anne Lee investigated the Wilmington house and arrested Mrs. Patsy Dederich, twenty-one, of 1396 Louis Street, Long Beach, as a material witness. Mrs. Dederich was caught as she attempted to flee through a rear door, according to police. She said she had submitted to an operation yesterday. She was taken to General Hospital for medical examination." (Los Angeles *Illustrated Daily News*, January 7, 1937.)

"At least one illegal operation occurs to every three confinements, it was revealed in an article by Gretta Palmer, appearing in the current issue of *Pictorial Review*. 'Not to Be Born' is the title of this daring, yet delicately written, article. In a foreword the editors of *Pictorial Review* announce that before deciding to publish Mrs. Palmer's article they had several hundred women

selected at random read it and offer suggestions. While some of these women objected to certain portions of the article, which were deleted before publication, there was no serious objection to the publication of the article, which will cause untold thousands to give thought to the illegal operations performed in this country. 'Every day twenty-two women in the United States die trying to avert bearing children,' says Mrs. Palmer. 'Writers and physicians have been telling women's clubs for years that our country has a shockingly high maternal mortality rate, compared with the rest of the world. . . . That between six and seven American women out of every thousand die in childbirth. They have not often told us that fully one-fourth of these fatalities are not genuine childbirth cases at all. They are deaths resulting from blundering efforts to destroy the child-to-be. The vast majority of them occur in the first three months of pregnancy.' Mrs. Palmer gives some astounding statistics concerning illegal operations and their results. These include: Approximately 700,000 abortions are performed in this country annually. There is one illegal operation to every five pregnancies. More than 8,000 women died from abortions every year in the United States. In 1890 there was one abortion to every seven confinements. Today the ratio is one to three. Sterility is the commonest after-effect of a 'successful' operation of this kind. Nine per cent of the women who have one abortion become sterile; 18 per cent of those who have two or more." (San Francisco *Call-Bulletin*, January 14, 1937.)

"Federal Judge Cosgrove next Monday morning, in Los Angeles, will pronounce judgment in the Government's case against Richard Diener of Oxnard, charged with using the mails to sell a patent medicine, which he represented falsely. Diener changed his plea of guilty after a jury had been selected to try the case and, through the advice of his attorney, Charles Blackstock, made application for probation. Before judgment is pronounced, Federal probation officers will submit to the court the

result of their investigation into Diener's record. As head of the Curarina Agency of Oxnard, Diener was charged with selling the medicine through an intensive mail-order campaign, representing that it would cure cancer, heart trouble, blood disease, rheumatism, and other ailments. Government chemists charge that the medicinal product contained none of the properties claimed for it." (*Ventura County Star*, December 3, 1936.) Diener and his product, Curarina, were mentioned in the *Journal of the American Medical Association*, February 29, 1936, page 724.

"Police are hunting a man who gave his name as 'Dr. Henry McCall,' Medico-Dental Building, when he passed a spurious check on Kern's Bakery for \$12. The check, signed with the name of Mrs. Irma Wilbur and drawn on the Hunter Square branch of the Bank of America, was passed December 12. The complaint was sworn to by Kern Monday." (*Stockton Record*, December 30, 1936.)

According to a news item printed in the *Los Angeles Illustrated Daily News*, December 31, 1936, Dr. Garnet King, 2025 South Grand Avenue, Los Angeles, assertedly has perfected an improvement in ether anesthesia. He is quoted as saying: "All I did was to devise a simple method of preheating ether so that it was drawn into the patient's lungs as a pure gas mixed with air or oxygen. Explosions are now impossible. There can be no ether pneumonia following the operation, and there is no resultant nausea. . . . When it was finally ready it was just a simple little apparatus, an ether container and a hot water thermos jacket. . . ." The records of the Board of Medical Examiners do not show anyone by the name of Garnet King licensed under the Medical Act.

"Because of insufficient evidence, Dr. Jack Smitherman was absolved of all blame Wednesday for the death of

21-year-old Virginia Sandefur, who died following an illegal operation December 1." (*Los Angeles New Age Dispatch*, December 18, 1936.)

"For the second time the State Supreme Court today denied the appeal of E. B. Hartman for a Writ of Habeas Corpus to release him from San Bernardino County jail, where he is serving a term for violating the State Medical Practice Act. He contended that he did not specify 'Doctor of Medicine' when he used the title doctor." (*Fresno Bee-Republican*, December 29, 1936.)

"Placed under \$5,000 bail by Justice Ernest Beam, Dr. Melvin R. Miranda, charged with two counts of negligent homicide and two counts of manslaughter in connection with the traffic death of Mr. and Mrs. M. J. Wilsey of Long Beach last Sunday, was in the county jail today, awaiting trial on December 15. He was arraigned yesterday in the Signal Hill Township Justice Court, and represented by Attorney Edward G. Haumesch. The bail was not met and Doctor Miranda was returned to the county jail by Investigator Tom Daniels of the Norwalk sheriff's office. Inquest into the death of the two Long Beach residents, who met their death while going to the aid of other motorists, was set for December 10." (*Long Beach Press-Telegram*, December 9, 1936.)

"Weird circumstances in the mysterious death of Ella Mae Clemmons, wealthy eccentric, who was known as the 'Christ Angel of Chinatown,' may never be explained. . . . Criminal procedure in the strange case was dropped yesterday when Hjalmar Groneman, the chiropractor who married Miss Clemmons on her virtual deathbed and laid claim to her entire estate, appeared for trial on a manslaughter indictment. Superior Judge Sylvain J. Lazarus

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

dismissed the case after hearing that the combined efforts of police and Department of Justice have failed to locate Charlotte Engberg, comely blond nurse and chief State witness. Judge Lazarus stated, however, that the dismissal does not give Groneman immunity. If Miss Engberg ever is found and the State decides to proceed anew, it can ask the Grand Jury for another indictment on the same charges. . . . Miss Engberg attended Miss Clemmons as nurse and was the State's sole witness on Groneman's alleged culpable negligence. . . . Shortly before the manslaughter indictment was returned, Groneman and the nurse announced they were engaged and would wed soon. Then Miss Engberg disappeared. It was brought out that she had lived with Groneman both before and after his marriage. . . ." (San Francisco Examiner, December 18, 1936.)

"For performing an illegal operation last August 27, which resulted in the death of Mrs. Hazel Scott, forty-three, Mrs. Regina Holscher, fifty-eight, yesterday was sentenced by Superior Judge Charles W. Fricke to a year in the county jail as condition to being granted five years' probation. In the probation report Mrs. Holscher admitted having performed at least one illegal operation each month for the last year." (Los Angeles Illustrated Daily News, December 19, 1936.)

Under date of December 21, United States Post Office Inspector C. W. B. Long reported that Matthew O. Wilkinson, Harold N. Baxley, and Curtis Yager were recently convicted of eyesight swindles. Matthew Wilkinson is featured in the 1930 report of the Board of Medical Examiners in the article entitled "Eyesight Swindlers."

In the nature of things youth cannot be aware of its latent powers.

"Seven Steps to the Undertaker" by Frank L. Rector, M. D.*—For the past six years the writer has devoted full time to the cancer educational field in a territory comprising the states of Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, Ohio, and Wisconsin. During this time the cancer problem has been discussed with hundreds of physicians and with thousands of laymen. Frequent attendance at the cancer exhibit of the American Society for the Control of Cancer at the Century of Progress, which was visited by 1,500,000 persons during its two years of operation, offered a unique opportunity for finding out what a vast cross section of the population was thinking about cancer. This experience has been augmented by frequent addresses to public groups with opportunity for questions from the floor.

As a result of these experiences, questions have been repeatedly asked by the laity and statements made by physicians that indicate fairly well the trend of thought of these two groups regarding cancer. It is believed that a frank discussion of the attitude toward the cancer problem as shown by certain physicians, which attitude is so at variance with known facts about the disease and so inimical to the patient's welfare, should do much to bring about a changed situation that will benefit the entire profession.

In justice to the large majority of physicians who have a right conception of the cancer problem, it should be said that the attitudes under discussion are usually those of physicians who have been in practice many years and whose experience with cancer in their early years of practice was discouraging. These older physicians have shown by their fallacious ideas that they have not kept pace with developments in the clinical and educational cancer field. Unfortunately, some of these physicians hold positions of influence and responsibility in medical organizations that cause the younger men of the profession to look to them

for leadership in scientific as well as organization problems. These erroneous and antiquated ideas concerning the relation of the public to the cancer problem will be discussed under seven headings, or steps, the following of which to their logical conclusion has suggested the title for this paper.

Step 1. "Efforts to enlighten the public about cancer only stimulate cancerphobia and increase morbid fears about the disease." As the basis of fear is ignorance, and as ignorance has its roots in mystery, it would seem logical to assume that fear would be banished when mystery is dispelled. The only way to overcome mystery and ignorance is by education. . . .

Step 2. "Cancer education drives the public to quacks." For hundreds of years there has been little change in the willingness of human beings to accept at face value the specious arguments of those with questionable goods to sell, whether these goods are of material value or service, as witness the prosperity of fake stock and bond salesmen. Just so the cancer quack flourishes because he offers a positive cure by treatment other than surgery which is so abhorrent to many people.

The physician who fails to tell his patient frankly what ethical medicine has done and can do for cancer is playing directly into the hands of these charlatans. . . .

Is not the implication for the profession clear in such a situation, and the neglect to satisfy the patient of ability to treat cancer as well as other diseases but another step in that patient's progress toward the undertaker?

Step 3. "The profession has no cure or even hope to offer the cancer patient." This attitude is utterly defenseless on the part of any physician engaged in the ethical practice of medicine. It places the physician expressing such views in the era represented by leeching, blood letting, wormy chestnuts, and rabbits' feet as therapeutic and preventive methods of medical practice.

It is a sad truth that more than half the cancer patients still seek medical aid for the first time after they are so involved that a cure cannot be expected. They do this because of ignorance and the fallacies and fears that beset them at these times. . . .

Instead of cancer being an incurable disease for which there is no hope for the patient, it is known to be curable when treated in early stages, and it can be palliated to the comfort of the patient in later stages. The physician who assumes a hopeless attitude toward his cancer patient is forcing him one step nearer the undertaker.

Step 4. "Treatment often increases the patient's suffering." Proper surgical therapy cannot be accused of increasing the cancer patient's suffering. Radiation sickness was a distressing condition with many patients until methods were perfected which eliminated it, except in those individuals who had an idiosyncrasy toward the rays of x-ray and radium. It is believed that this group of patients is no larger than that found with idiosyncrasies against many drugs.

Today no physician with experience in cancer therapy hesitates to give indicated treatment for fear of increasing the physical suffering of the patient. . . .

Step 5. "By telling the patient the truth, his condition is often aggravated." This fallacious argument has been answered in part earlier in this paper. If the medical profession is not willing to tell the public the facts about cancer as they do about other diseases, such as tuberculosis and diphtheria, they can expect many people will worry over the problem. On the other hand, those physicians and hospitals making a general practice of telling patients frankly when they have the disease, report only the fullest cooperation of the patient in his treatment. Barring the occasional neurotic who has a new phobia at frequent intervals, the average intelligent patient is inclined to take his illness sensibly. . . .

Step 6. "The patient will not coöperate in treatment." It is doubtful if more cancer patients fail to coöperate in treatment than do patients with other diseases, such as tuberculosis, venereal disease, heart disease, and others where the treatment is of necessity prolonged. The average patient is anxious to get well and becomes restless, especially during convalescence.

When it is explained convincingly to the cancer patient that his treatment, particularly if it is radiotherapeutic in character, must be prolonged far beyond apparent recovery, and in any event that he must coöperate with the physician for his own safety, he will be found as responsive as the average patient. . . .

Step 7. "A watchful-waiting attitude on the part of the physician is often the best method to pursue." This argument advanced by some physicians is the most fallacious and damaging to the patient's welfare of all those discussed. It would be just as logical in the face of an epidemic of smallpox or diphtheria for a physician to wait for positive symptoms of the disease before vaccinating or immunizing his patients. Some physicians may be constitutionally opposed to discussing the patient's condition in his presence, but this type will pass as the public becomes better informed on health and medical matters, and patronizes only those physicians who will take them into their confidence.

The physician who fails immediately to utilize accepted methods for obtaining a diagnosis of his patient's suspected cancer, waiting for more positive signs of the disease, is by each day's delay lessening that patient's chance of survival. The patient may be excused for his delay in seeking medical aid because of ignorance of the significance of the symptoms; but for the physician to temporize with the case after being consulted is inexcusable from every point of view. . . .

An effort has been made to criticize constructively some of the retarding factors in the cancer education program. These factors are similar to those encountered in other health education movements. It will be remembered that many physicians in the beginning opposed the tuberculosis program as tending to alarm the laity unduly, and urged

that methods for its prevention and control be *not* discussed in public. In many ways the cancer problem today parallels the tuberculosis program of thirty years ago.

It is really amazing the views held by some physicians about cancer. These vary from a strong leaning toward the fallacy that the mind has an influence over the growth or retardation of tumor tissue to the belief that the disease is contagious if not directly inherited. When pressed for proof of these views, it is always lacking.

With the new information that is accumulating daily, and with the intelligent lay interest becoming manifest in a better control of the cancer problem, the outlook is bright for a marked reduction in deaths from this disease. The medical profession has the opportunity to write another brilliant chapter in the conquest over disease by accepting whole-heartedly the responsibility for a service which it alone can render.

IN ADVISING PATIENTS ON SMOKING

WITH the many and varied claims made for cigarettes, you can be of assistance to your patients. With your scientific knowledge, you can discriminate between mere claims and basic facts.

Due to the use of diethylene glycol instead of glycerine, Philip Morris have been proved* less irritating than other cigarettes... proved so conclusively that the medical profession recognizes the substantial nature of this improvement in cigarette manufacture.

Test Philip Morris on patients suffering from congestion of the nose and throat due to smoking. Verify for yourself Philip Morris superiority.

PROFESSIONAL PROTECTION

A DOCTOR SAYS:

"No company could do more to protect the practice of its assured and also relieve him of the worry and inconvenience involved in such a claim."

THE

MEDICAL PROTECTIVE COMPANY

OF FORT WAYNE, INDIANA

WHEATON, ILLINOIS

Menaces to Eyesight.—Indiscriminate use of weight reducers, hair dyes, and depilatories is causing serious injury to eyesight in the United States, according to a warning by Dr. Walter I. Lillie, in the current issue of *The Sight-Saving Review*, quarterly journal of the National Society for Prevention of Blindness.

Case stories of eye tragedies among his patients are cited by Doctor Lillie, and he gives the trade names of the "beauty products" which the victims used. Doctor Lillie is a practicing ophthalmologist in Philadelphia, and a member of the Department of Ophthalmology of the Temple University School of Medicine there. Writing on "Cosmetics Detrimental to Vision," he says:

"Individuals who use cosmetics are unwittingly subjecting themselves to visual dangers. We are all potential victims, because the present antiquated Food and Drug Act, passed in 1906, only requires the manufacturers of food and drugs to properly label their products, but does not penalize the acts of adulteration and misbranding. False and fraudulent therapeutic claims must be proved before the product can be removed from the market.

"These two little words, 'and fraudulent,' compel the Government to prove that the manufacturer knows the customer is being swindled. This has prevented any adequate control over quack or dangerous remedies. Extraneous advertising of these products through the newspapers, magazines, and radio is without federal control, and because of this we are constantly reminded of the wonderful benefits and cures that will be derived from their use.

"Today the billion-dollar-a-year cosmetic industry is not subject to any federal regulations unless the labels bear medicinal claims, which, of course, never occurs. There is no legal way to protect the public against dangerous cosmetics. Toilet preparations which are known to be harmful by the medical profession cannot be taken off the market regardless of any disfigurement or injury they may inflict. Although poisonous cosmetics that ravage their users by paralyzing, blinding or disfiguring them are the exception rather than the rule, the medical pro-

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

**Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack
and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.**

Zera E. Bolin, M.D., 490 Post Street, San Francisco, California. . . .

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

Mailing containers sent on request. Special delivery postage insures prompt, accurate service.

fession should be alert to the possibilities and probabilities of visual and bodily damage which may result from their use.

"The untoward visual effects may be temporary or permanent, depending upon the nature of the ingredient or the amount used, and the tolerance of the individual. The eyes are usually affected in one of two ways, either through direct contact with the preparation or indirectly through the absorption of the poisonous ingredient in the body. Three groups of cosmetics have the potentiality of producing severe ocular damage, namely, (1) weight-reducing preparations, (2) hair dyes, and (3) depilatory ointments.

"The present Administration has asked for a new Food and Drug Act which will give consumers better protection than the present antiquated pure food law affords. The officials of the Department of Agriculture have drafted the Copeland Bill (erroneously called the Tugwell Bill), which is proposed in the interest of the public and the honest manufacturer. This Act is to afford federal control of the manufacturing, labeling, selling, advertising, and shipping of prepared foods, drugs, and cosmetics.

"This bill is actively supported by the American Medical Association, American Federation of Labor, the National Congress of Parents and Teachers, and eleven other national women's organizations. A powerful opposition lobby has been organized and is sponsored by the Proprietary Association of America and numerous allied groups. Their apparent aim is to keep the present inadequate federal regulations unchanged, and so far their efforts have delayed constructive legislative action.

"A new law must be passed to insure the public of a deserved protection. We as individuals and as members of medical organizations should put forth every effort to obtain adequate legislation against the promiscuous sale and use of poisonous foods, drugs, and cosmetics."

Medicine absorbs the physician's whole being because it is concerned with the entire human organism.—Goethe.

A VETERAN'S BIRTHDAY...

Five years ago Abbott and a cooperating laboratory offered Haliver Oil with Viosterol to the physician. It was born of original research at a time when much uncertainty surrounded the potency of many of the vitamin products on the market. Thereafter the physician could prescribe Abbott's Haliver Oil with complete assurance that his patients would get all those vitamins he intended them to have. And he did, after Abbott's ethical promotion presented him with the facts.

Today the story is unchanged. (Today, too, it is no secret that deficient vitamin products are still offered for sale.) Abbott goes direct to the source in the North Pacific and assumes complete control of production. No outside factor beclouds certainty of quality of our haliver products. After the fish are caught their freshly extracted livers are packed in ice and salt and rushed to our modern refinery in Seattle for preliminary assaying. Only fish oils of the highest quality are used.

Full vitamin potency is proved by rigid bioassays conducted in a fully equipped, completely modern laboratory under conditions making for the utmost scientific accuracy. All label claims for vitamin content are based solely upon the bioassay results, but as additional checks to accuracy, both colorimetric and spectroscopic assays are applied to each lot at Abbott Laboratories.

Prescribe Abbott's Haliver Oil with Viosterol routinely for lactating or expectant mothers, and all other patients who require additional Vitamins A and D. Available at prescription pharmacies in soft, tasteless capsules in boxes of 25, 50, 100 and 250. They are also available in 10-cc. and 50-cc. vials with special droppers. Adequate Treatment of Pernicious Anemia

● Of paramount importance in the treatment of pernicious anemia is the administration of adequate antianemic material, such as is contained in liver, to restore hemoglobin and red blood cell levels.

In cases where there is evidence that sub-acute combined degeneration of the spinal cord is present, therapy must be adequate to arrest completely all progress of the cord

degeneration. Adequate doses of solutions of liver extract can be conveniently given by parenteral injection.

For this purpose the following preparations are offered:

Solution Liver Extract Concentrated, Lilly—Supplied in 10-cc. rubber-stoppered ampoules and in packages of four 3-cc. rubber-stoppered ampoules.

Solution Liver Extract, Lilly—Supplied in 10-cc. rubber-stoppered ampoules.

THE MILL OF THE FIFTY-SECOND CALIFORNIA LEGISLATURE

Tentative Report on Bills Introduced.—At this writing it is not possible to give much information concerning proposed laws with public health implications which, up to the present, have been submitted to the Fifty-second California Legislature, now in session; because most of the important measures are still in their formative drafts.

At a meeting of the Council held in San Francisco on January 16, Dr. Junius B. Harris of Sacramento, chairman of the California Medical Association Committee on Public Policy and Legislation, gave a bird's-eye view of the legislative situation, and the picture he painted was in line with former experiences. The Council minutes record the action taken by that body in its all-day session.*

* * *

Three Important Measures: Medical Practice Act Codification; Medical Service Associations; Hospitalization Plan.—Three measures, in which the members of the California Medical Association have a special interest at this time, are:

1. The Medical Practice Act, as revised by the Code Commission. Through conference between representatives of the State Board of Medical Examiners, the California Medical Association and of the State Code Commission, it is hoped that the laws governing medical practice, in the new code, have been clarified without in any way detracting from their power.

2. The proposed law governing Medical Service Associations, as prepared by the Council's Special Committee and legal counsel, was carefully considered by the Council, section by section, and authority given to submit it to the Legislature. (See Item 13 in Council minutes.)

One or more measures of somewhat similar purpose have already been introduced on behalf of interests whose identity is not known. More of these in later issues.

3. A proposed Hospital Service law, sponsored by the Associated Hospitals of Southern California, was read, discussed and approved by the Council, and the chairman of the Los Angeles

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

* Council minutes are printed in this issue, on page 120.

County Medical Association Committee, Dr. William H. Kiger, was given authority to have the bill presented to the Legislature. This bill will take the place of Assembly Bill 246, which was enacted by the previous legislature, and contains provisions which the State Insurance Commissioner feels will add to its value and safeguards.

* * *

Other Proposed Laws.—Six skeleton bills to amend Medical Practice Act:

Among other items of proposed legislation, it may be of interest to note that one assemblyman has introduced a half-dozen "skeleton bills" to amend the Medical Practice Act; the entire texts of which measures, at the time of this writing, contain nothing more than the meager language:

An act to amend Chapter 5 of the Business and Professions Code, relating to the practice of medicine and surgery, and other modes of treating the sick or afflicted.

The people of the State of California do enact as follows:
1 Section 1.

What this assemblyman proposes later, on behalf of himself and friends, to insert in his array of measures, remains to be seen!

* * *

Clinical Histories of Patients No Longer Confidential(?):

Assembly Bill No. 385 is not long, and will probably shock most physicians and hospitals, who are prone to look upon history records as confidential communications. It is a joint presentation of seven assemblymen; and because of its comparative brevity, it is here printed in full:

ASSEMBLY BILL No. 385

Introduced by Messrs. Clark, Peek, Hornblower, Lore, Pelletier, Hawkins, and Rosenthal
January 13, 1937

Referred to Committee on Hospitals and Asylums

An act to add section 10½ to the Workmen's Compensation, Insurance and Safety Act of 1917, relating to records of persons receiving compensation thereunder.

The people of the State of California do enact as follows:

SECTION 1. A new section is hereby added to the Workmen's Compensation, Insurance and Safety Act of 1917, to be numbered Section 10½ and to read as follows:

Sec. 10½. All records of any hospital, clinic, sanitarium, physician, surgeon, or other person or institution in respect to services rendered to any person under the provisions of Section 6 of this Act, including but not restricted to x-rays and histories of injuries and diagnoses, shall be exhibited to the patient and to any person authorized in writing by him to examine the same. Any such person or patient shall be permitted to make copies of such records, including, but not restricted to, photostatic copies. Violation of any of the provision of this section shall constitute a misdemeanor.

* * *

Assembly Bill No. 384, a bill couched almost in the same language, is entitled:

An act to add Section 4055.5 to the Labor Code, relating to records of persons receiving compensation thereunder.

The people of the State of California do enact as follows:

* * *

False Advertising by Radio:

Then there is Assembly Bill No. 288 which, if enacted, may apply to some of the atrocious mis-

representations so frequently heard in radio broadcasts concerning curative agents. It is entitled:

An act to add Section 654d to the Penal Code, relating to false advertising by radio, and providing penalties for the violation thereof.

The people of the State of California do enact as follows:

* * *

Milk Production and Distribution:

Two bills having to do with milk (Heisinger Assembly Bill 50 and Thorp Assembly Bill 77) are commented upon by Dr. J. C. Geiger in the Letters department of this issue. (See page 132.)

* * *

Pay Patients in County Hospitals:

Assembly Bill No. 51, introduced by Mr. Heisinger, has been referred to the Committee on County Government, its short title being "County Hospitals Admission Amendment." It would permit a county board of supervisors to "provide for the admission of pay patients to the county hospital."

* * *

Narcotic and Other Measures:

Among other bills are several which deal with narcotic regulations, the licensing of clinical laboratory technologists and technicians, and various public health matters.

These and other proposed laws will receive comment in later issues of the OFFICIAL JOURNAL.

A NATIONAL DEPARTMENT OF PUBLIC HEALTH

The Effort Twenty-five Years Ago.—About twenty-five years ago considerable effort was made by the medical profession throughout the country to secure the enactment of legislation that would provide for an additional department—that of Public Health—to be represented in the cabinet of the President of the United States. Those endeavors, however, made very little impression upon Congress or the lay public. As a matter of fact, the attempt brought such a disheartening response that some who had enlisted in the cause came to the conclusion that it was a proposition almost permanently hopeless.

In the same issue of the OFFICIAL JOURNAL,* in which these comments appear, is also printed a paragraph written twenty-five years ago by the late Philip Mills Jones, as follows:

Owen Bill.—A number of requests for a copy of the last Owen bill to create a Department of Public Health have been received, and as the matter is of the greatest importance to public health, the *Journal* elsewhere in this issue, prints the bill in full. It will probably be some time before the Congress will enact any law of this nature, and it is quite possible that when such a law is finally passed it will differ somewhat from the present proposed measure . . . California State Journal of Medicine, Vol. X, No. 2, February, 1912.

* * *

Different Attitude With Changing Times.—However, times have changed, and with the social unrest of the past few years, a shift of view has

* See Twenty-five Years Ago department, on page 144.

taken place, and given rise to a movement to bring into existence not one, but two or more new administrative departments in the national government, each to include bureaus doing work in associated fields, but which, at the present time, have places in departments far apart in their basic organization and activities.

* * *

Recent Action of the American Medical Association Trustees.—In January, at a special meeting of the Board of Trustees of the American Medical Association, that body adopted the following resolutions worthy of the thought of every licensed physician and surgeon:

Recognizing that committees of the Senate and of the House of Representatives of the United States Government, and a special committee appointed by the President are at this time concerning themselves with the reorganization of government activities with a view to greater efficiency and economy, and recognizing also that the President, in his opening address to Congress, indicated that he would shortly present to the Congress recommendations for such reorganization of governmental activities in the executive branches, and recognizing, moreover, the great desirability that all activities of the Federal Government having to do with the promotion of health and the prevention of disease might with advantage be consolidated in one department and under one head, the Board of Trustees of the American Medical Association would recommend that such health activities as now exist be so consolidated in a single department which would not, however, be subservient to any charitable, conservatory or other governmental interest. It has been repeatedly said that public health work is the first problem of the State. It is the opinion of the Board of Trustees that health activities of the Government, except those concerned with the military establishments, should not be subservient to any other departmental interests. This reorganization and consolidation of medical departments need not, under present circumstances, involve any expansion or extension of governmental health activities, but should serve actually to consolidate and thus to eliminate such duplications as exist. It is also the view of the Board of Trustees that the supervision and direction of such medical or health department should be in the hands of a competently trained physician, experienced in executive administration.

In which statement we would call particular attention to the words:

"... the Board of Trustees of the American Medical Association would recommend that such health activities as now exist be so consolidated in a single department which would not, however, be subservient to any charitable, conservatory, or other governmental interest."

* * *

County Medical Society Resolutions.—In resolutions, which later may be considered by component county societies of the California Medical Association, the above requisites should always be emphasized. We must all acknowledge that the experiences of the last several years, in California and other states of the Union, have amply and repeatedly demonstrated to physicians the real and serious danger to high standards of medical practice when lay theorists—whether professors of economics, statisticians, directors of foundations, advanced social-service workers, or paid or free-lance propagandists—are given positions of responsibility in which they have direct or indirect supervision over the professional work of physicians and surgeons.

A National Department of Public Health With Its Secretary in the President's Cabinet Is Needed.—The United States of America needs very much a national Department of Public Health, having as its head "a competently trained physician, experienced in executive administration"; but it would be a deplorable error to link up the United States Public Health Service, and other affiliated agencies in preventive and curative medicine, with social welfare and similar groups; which, because of more intimate contacts with political influences, would be almost certain to warp and handicap real progress in work for the national public health.

* * *

California Medical Association Council Is in Accord With the American Medical Association Policy.—In view of the action taken by the Board of Trustees of the American Medical Association* (with which the Council of the California Medical Association is in full sympathy), it is quite in order for every component county society to pass proper resolutions, to be sent to Senators Hiram Johnson and William McAdoo, and to the congressmen of their respective districts, with an explanatory letter of transmittal asking coöperation and support for a national Department of Public Health organized along lines as above indicated. Members or committees in component county societies, therefore, who are interested should confer with one another and draw up such resolutions to be presented at early meetings. If preliminary drafts of resolutions are sent to the Association Secretary, he will be glad to advise and suggest. In any case, copies of resolutions, with the names of senators and congressmen to whom they have been sent, should be forwarded to the Central Office of the Association, at San Francisco.

"SECURITY FOR THE DOCTOR MEANS INSECURITY FOR THE PATIENT"

President of Medical Society of State of New York Speaks.—A newspaper item which recently appeared in the *Syracuse Herald*, containing excerpts from an address by Dr. Floyd B. Winslow, president of the Medical Society of the State of New York, has been called to our attention. Doctor Winslow's incisive remarks are worthy of perusal and are submitted for the consideration of the readers of *CALIFORNIA AND WESTERN MEDICINE*. Quotations follow:

Dr. Floyd B. Winslow of Rochester, President of the Medical Society of the State of New York, is assailing attempts to "foist" compulsory sickness insurance in this country.

In a speech to 150 physicians gathered in annual convention from seven upstate counties, Doctor Winslow said:

"Security for the doctor means insecurity for the patient."

He characterized as socialized medicine certain plans being promoted for compulsory sickness insurance.

"The advocates of these measures," he said, "lure the profession with the siren song of bureaucratic jobs, as—

* See *Journal of the American Medical Association*, January 16, 1937, page 208.

sured income—security—false security. We do not want to be secure. We want to remain insecure. We want to be required to continue to give our very best to every patient, or lose out in the gentlemanly competition which exists within our ranks.

"This is an incentive that operates to our insecurity, but to the security to the patient. We prefer the discipline of private practice which keeps us on our toes, to an assured income under bureaucratic control where our highest ambition is more likely to be to keep ourselves solid with the politicians who have taken over the job of running our profession."

UNITED STATES PUBLIC HEALTH SERVICE: ITS REPORT FOR THE YEAR 1936

How the "Marine Hospital Service" Has Grown.—From a Federal act, originally called the Marine Hospital Service law, signed on July 16, 1798, by John Adams, second president of the United States, and designed to give medical care to sick and injured seamen (for in those infant days of the Republic the mercantile vessels which made the Atlantic coast stations their home ports were a big factor in the prosperity of the Original Colonies), there has come into being during the succeeding 138 years a department known as the United States Public Health Service. It still carries on its original function, conducting twenty-five marine hospitals and 154 relief ports where merchant seamen may receive care as in Colonial days.

Two Federal narcotic farms, and Federal penal and correctional institutions, also receive its medical services, as do employees in the railway mail service. In addition, there has been developed, from the first beginnings, a Federal Public Health Service of great scope and efficiency; and in the report of Surgeon-General Thomas Parran, Jr., who, on April 6, 1936, succeeded his predecessor, Hugh S. Cumming, some of the major activities are outlined and may be worthy of further brief comment.

* * *

Decreasing Mortality Rates of Recent Years. New low death rates were recorded, in the preceding year, for typhoid fever, diphtheria and for infants under one year of age. The decrease in the death rate of tuberculosis and communicable diseases continues.

Chronic diseases, such as heart afflictions and cancer, baffle Federal and private physicians alike.

Three human cases of bubonic plague were reported from Western States, where rodent infestation is endemic. Smallpox was credited with 8,000 cases, many times more than should be in a supposedly enlightened age.

* * *

Research Activities.—The research activities of the United States Public Health Service included special studies of diseases such as "cancer, heart disease, malaria, Rocky Mountain spotted fever, poliomyelitis, leprosy, tularemia, plague, bacteriology, prophylaxis and therapeutics, pharmacology, zoölogy, and chemistry, and such additional subjects as industrial diseases, nutrition, child hygiene, dental investigations, milk sanitation, and stream pollution."

The Fight Against Syphilis and Gonorrhea. Mention is made of the greater attention which the Service is giving to venereal diseases, thanks largely to Surgeon-General Parran, who observes in his report:

When these diseases are brought out into the open, freed from the medieval concept of condign punishment for moral transgressions, and are dealt with as any other highly communicable diseases, the way is open to eradicate them just as we have stamped out other dangerous infections.

* * *

Medical Economic Surveys.—Another activity which should be of interest to readers, because of the Association funds, which, in conjunction with federal monies, have been expended on the California Medical Economic Survey, has to do with similar studies in other parts of the Union, concerning which it is stated:

The Public Health Service is engaged in the analysis of the enormous amount of data secured in the health inventory conducted in 1935 and 1936. This study included a survey of disabling illness, physical impairments, and facilities for medical care among 865,000 families in ninety cities and twenty-three rural counties—the most comprehensive survey of the kind ever undertaken in this country.

* * *

High Scientific Standard of United States Public Health Service Should Be Maintained.

From the above it is evident that the record of achievement of this medical branch of the Federal Government is one in which not only the Service personnel, but all physicians and citizens may take real pride. These beneficent results have been brought about in good part because, in the last 138 years, the United States Public Health Service has been permitted to go forward in the fulfillment of its functions, under the leadership of medical executives who have made the highest standards of scientific medicine an integral part of the Department's aims and work. During this period of more than a century, the Service has been able to remain free from political and propagandist influence, and the best interests of the States of the Union demand that it must so remain. Licensed physicians everywhere should give whole-hearted and active support to that end.

MORE CONCERNING AUTOMOBILE ACCIDENTS AND "VEHICIDES"

Previous Comment on the Subject.—In the October, 1936 issue, on page 307, of CALIFORNIA AND WESTERN MEDICINE, the subject of automobile accidents was commented upon, and it was stated that in the year 1935, among 1,285,000 accidents occurring in automobile traffic in the United States, a total of 37,000 citizens had been fatally injured!

Some reasons for this appalling record were briefly indicated, the suggestion being offered that here was a problem to which county medical societies and their auxiliaries should give serious attention.

Ratings of Ten California Cities.—For the information of readers, the figures for the ten California cities listed in the report on 131 municipalities are given, the New York City, Chicago, and Philadelphia tabulations also being appended for contrast. (See table above.)

Is it necessary to add that mortality statistics such as the above provide food for serious thought?

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 119.

Health at New Orleans.—Telegraphic reports to the United States Department of Commerce from eighty-six cities with a total population of 37,000,000, for the week ended December 5, indicate that the highest mortality rate (21.3) appeared for New Orleans and that the rate for the group of cities as a whole was 12.2. The mortality rate for New Orleans for the corresponding period last year was 19.4 and for the group of cities, 12.2. The annual rate for eighty-six cities for the forty-nine weeks of 1936 was 12 as against a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

EDITORIAL COMMENT†

RECENT IMPROVEMENTS IN METHODS OF BIO-ASSAY*

Methods of performing biologic assay have recently been receiving considerable attention. The importance of the studies by Trevan¹ and Burn,² which make it possible to place this subject on a sound scientific and statistical basis, is being more generally appreciated.

The older method of injecting a series of animals with gradually increasing doses of the substance to be tested was usually not productive of a sharp end-point; frequently an animal receiving one of the larger doses would not react, while one receiving a smaller dose would give a positive test, thus leaving no definite level for the end-point. Anyone who has done much work in the biological laboratory knows that such a result is more common than to find a sharp demarcation in a series. Trevan and Burn have pointed out that animal variation must be considered in seeking biologic end-points, and that the only way to accomplish this is to inject a large number of animals with the same (submaximal) dose of the substance to be tested. The true end-point will then be represented by the percentage of reaction at that dose. If the percentage of reaction at several levels is determined, a toxicity curve can be constructed which will be characteristic of the reaction of that species to that drug. The percentage of possible error at the various levels can also be computed, using a formula which considers the number of animals used, the number of positive and negative reactions, and the size of the dose. The application of these concepts to older work based upon biologic assay has been productive of some surprising results.

2 Burn, J. H.: Errors of Biological Assay, Physiol. Rev., 10:146-169, 1930.

A recent example is some work with the clinical modification of the Reid-Hunt acetonitrile test, which was said to indicate the presence of an increased amount of thyroid, or of thyreotropic hormone from the anterior pituitary, in the blood stream. The test was accomplished by noting the effect of injections of the blood serum to be tested upon the resistance of white mice to acetonitrile. Recent work³ applying the methods of bio-assay, as advocated by Trevan and Burn, to this test has shown it to be without any clinical value.

Another important fact requiring consideration is the number of preparations that are now on the market with potency expressed in various animal units. It is obvious that unless the proper methods of bio-assay are used, the potency of the marketed preparation will vary as much as the resistance of the animals used, and it would be of interest, therefore, to have more details concerning methods of biological assay from pharmaceutical houses offering assayed substances for sale.

THE PHYSICIAN: SCIENTIST OR ARTIST?

Ignoring for the moment many secondary meanings, science may be defined as the classification and coordination of factual knowledge; art as the utilization or application of knowledge to accomplish desired results. In the former case, knowledge is static; in the latter it is dynamic.

If the foregoing definitions are correct, it is evident that the present-day tendency to regard medicine as strictly a science is ill advised. For reasons of policy, perhaps such a conception is well enough. But any scheme of classification that fails to consider the claims of art in the premises does violence to a fair appraisal of the question.

Most basic knowledge concerning the structure and functions of the human body obviously is derived from science. Equally obviously the practical application of that knowledge falls within the province of art.

All living things are manifestations of art in the sense that their interpretation may be approached only through the artistic faculties. It is not possible to apply to them the cold, formal, unchanging rules and methods of science. Science confines itself to the material, and refuses to concede that the difference between animate and inanimate matter is in any important respect significant. Conclusions adduced from the study of matter, even its minutest subdivisions, refer exclusively to physical states existing at certain definite moments of time, not to the constantly changing conditions which constitute the very essence of living processes. Science seeks only data that are fixed and stable relative to the material elements which form life's medium of expression.

To be sure, matter is the essential basis of life as mortals know it. But there is a profound and fundamental distinction between living and non-living matter, which in the very nature of things

science does not undertake to investigate and explain. Science relies on measurement, mathematical exactness. These depend upon sense perception. It follows that science cannot deal with the intangible factors involved in determining the normality or abnormality of the actions and reactions of living organisms, ordinarily called symptoms. Symptoms point the way, the only way, to diagnosis. And diagnosis is the heart of medical practice.

The complex problems relating to the interpretation of life and its functional activities lie wholly within the sphere of the artistic. This higher plane is the *fons et origo* of those familiar, but scientifically undemonstrable mental processes, analysis, abstract reasoning, logical deduction; and here alone the power to differentiate the abnormal from the normal, to select the one true from many possible conclusions, may operate. Imagination, intuition, inference, judgment—these are faculties belonging to the realm of art as truly as those employed in the appreciation of beauty or the enjoyment of great music.

A master painting is composed of material substance—canvas, pigments, oil. The revelations it makes to the cultured beholder are something other and more. The subtle qualities of perspective, harmony, charm, are in no sense identical with the physical components, however intimately dependent on them.

Until the mystery of life and the riddle of its meaning are solved, the vital phenomena of health and disease cannot be relegated to the domain of science where the yardstick reigns and demonstration by the physical senses is the court of last appeal. Even biology, the so-called "science of life," tacitly recognizes the dilemma and evades it by boldly assuming the fact of life, without claiming to comprehend, much less to explain it.

Medicine is both an art and a science. Any comparison as to relative importance would be invidious. Whether consciously or unconsciously, the physician in the pursuit of his daily duties must needs be an exponent of art no less than of science. Realization of this truth should be an inspiration as well as a constant incentive.

The Automatic Control of Radium.—At the Westminster Hospital, where special attention has been given to radium therapy for some time, an important advance in technique has been made. The new installation incorporates a system of distant control for the better protection of operators and has allowed larger "bombs" to be used. Additional radium has been acquired to give effect to the conclusion earlier reached by the surgeons in charge of the radiotherapy department that deeper penetration can be obtained by removing the radium to a greater distance from the point of application. Four grams of radium, valued at about \$200,000, is used and is carried alternately by two bombs. By a system of automatic electrical control the radium in its container can be lifted from a leaden safe into one of the bombs and swung into position over the patient. The electrical switchboard is situated fourteen feet from the patient's couch. The two bombs and the radium container are made of a heavy ray-proof metallic compound recently invented. The installation, which has involved months of experimental construction and special tools, has cost about \$4,000 apart from the radium.

PULMONARY EMBOLISM*

By E. RICHMOND WARE, M.D.

AND

LEWIS T. BULLOCK, M.D.†
Los Angeles

DISCUSSION by Donald J. Frick, M.D., Los Angeles;
Roy E. Thomas, M.D., Los Angeles; Philip H. Pierson,
M.D., San Francisco.

PULMONARY embolism is a frequent vascular accident which is too seldom detected before the patient reaches the autopsy table. A review of 236 chronologic necropsied cases occurring in the Los Angeles County General Hospital during the years 1931 to 1935, inclusive, has furnished us with the data upon which this discussion is based. Excluding the cases autopsied by the coroner, pulmonary emboli were found in 2.6 per cent of all necropsies. These autopsies were done by many individuals employing no special or uniform technique in searching for pulmonary emboli. There were many more cases of pulmonary infarcts and abscesses, and many of these were undoubtedly embolic; but no cases were included unless the embolus was described by the pathologists. Therefore, there were certainly numerous emboli which were not included in this incidence of 2.6 per cent. Many nonfatal cases were reviewed, but due to possible errors in diagnosis these were not analyzed statistically.

Although this condition is generally believed to be primarily a postoperative surgical complication, our series has amply demonstrated that a relatively small proportion of pulmonary emboli occur after surgical procedures, and that even in these cases there are usually accessory etiologic factors which are of primary importance. Autopsy analyses combined with clinical studies indicate that these accidents are frequently multiple, often unrecognized and are not necessarily fatal. In instances where death is not immediate, a clinical picture is usually presented which has certain fairly definite diagnostic characteristics.

CLINICAL MATERIAL FOR THIS STUDY

Our statistical information will be briefly reviewed in order to illustrate certain important conclusions. In this series of 236 cases there was an equal division between the sexes, there being 119 males and 117 females. Eighty-one per cent occurred after the age of forty. There were but four patients under twenty, and this is striking, considering the large number of children treated in this institution, where 17½ per cent of all admissions, excluding new-borns, were under sixteen years of age. The four cases under twenty were all associated with an active infectious process: two with cerebral sinus thrombosis following otitis

media, one with bacterial endocarditis, and one with rheumatic myocarditis complicated by jugular thrombosis. Where the embolus was unilateral the right pulmonary artery was involved more than twice as often as the left (sixty-six to twenty-nine), but in an equal number of cases (ninety-two) emboli were found on both sides. The main trunk was occluded in thirty-one instances, and in eighteen the location was not clearly defined. The arteries to the lower lobes were affected more frequently than those to the upper. It is of interest to note that multiple emboli were found in over one-half of the cases of the entire series (137). Forty-nine per cent of the total series developed pulmonary infarction, and this was most frequent in the right lower lobe. Icterus of the sclerae was present in twenty-two cases, and all but one of these had one or more pulmonary infarcts. In 84 per cent the pulmonary emboli were considered by the pathologist to be the primary or contributing cause of death.

INCIDENCE IN THE CHILDREN'S HOSPITAL
OF LOS ANGELES

We obtained further information on the rarity of this condition in patients under the age of thirteen from the Children's Hospital of Los Angeles. Between January, 1922, and June, 1936, there were 44,317 admissions. Between January, 1928, and June, 1936, there were 1,200 autopsies. In this total series there were only five cases in which pulmonary embolism was a consideration. There were two cases of sudden death a few hours after operation in which embolism was considered, but the recorded findings (without autopsy) did not support this diagnosis. There was one case of sudden death following a transfusion, which was given through a needle previously used for twenty hours for a continuous infusion of saline, in which thrombi were described only on microscopic sections of the lung. In a similar case, which also had a severe pneumonia, a "thrombus," one-fourth centimeter in diameter, was found in a pulmonary artery. In one case of infected circumcision, and staphylococcus septicemia, multiple abscesses in the lung were considered to be embolic in origin. There were, then, in this large group from the Children's Hospital, no cases that were clinically acceptable or in which a gross pulmonary embolus was identified at autopsy.

DIVISION OF PULMONARY EMBOLI INTO
THREE GROUPS

For purposes of comparison we have divided the cases of pulmonary emboli into three groups: those treated medically, 65 per cent; those following operation, 27 per cent; and those following trauma, 8 per cent. The most striking feature in the entire series—and this was, of course, most pronounced in the medical group—was the large number of cardiac cases. Thirty-five per cent had definite signs of decompensation, and another 17 per cent showed marked anatomical changes in the heart without decompensation. This represents 52 per cent of the entire series which suffered from severe cardiac disease. The incidence of pulmonary infarction was exceptionally high in

* Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

† From the Department of Medicine, Medical School of the University of Southern California.

We wish to thank Dr. Newton G. Evans and the Pathological Department of the Los Angeles General Hospital for the use of the autopsy records.

Fig. 1.—A. Three-foot anteroposterior view of chest three days after characteristic attack of pulmonary embolism. B. Three-foot anteroposterior view of chest twenty days after Film A. Note general cardiac enlargement and prominent pulmonary conus shadow in the first film. In the second film these have disappeared.

those suffering from congestive failure. These facts indicate that patients with cardiac disease, and in particular those with decompensation, are constantly candidates for pulmonary emboli. These are often small, frequently are not diagnosed, and are the reason for the multiple pulmonary infarctions so often seen at autopsy. In the surgical cases the embolus occurred most frequently between the fourth and the thirteenth day, with an average of eleven days. However, three were recorded as early as the first, and one as late as the thirty-first postoperative day. The time of appearance of the embolus, following trauma, averaged seventeen days.

SUPPURATION AS A CAUSATIVE FACTOR

In the total group of 236 the element of suppurations appeared to be an important causative factor. Frank collections of pus were discovered in fifty-two instances—twenty-nine in the surgical group of sixty-four, and twenty-three in the medical group of 153. Of these fifty-two, the location of the venous thrombosis was found in twenty-four instances, and in twelve of these the veins involved were directly in contact with the abscess. This suggests that the suppurative process was at times responsible for the formation of the localized venous thrombus. The incidence of abdominal suppuration was high—thirty-eight out of the fifty-two. Thirteen of these cases also had marked cardiac pathology or decompensation, indicating how combined factors may operate in a single case. It is interesting that the twenty-three cases of abscess in the medical group were candidates for surgery, but developed the pulmonary embolus before surgical intervention.

ACUTE PERIPHERAL THROMBOPHLEBITIS

We attempted to determine how often an acute peripheral thrombophlebitis might be considered the primary source of the embolus. There were only eleven such cases in the entire group. These figures are well in line with those reported by others, which indicate that fatal pulmonary embolism is not a common complication of an acute thrombophlebitis. The inflammatory process within

the vein sets up a reaction producing relatively firm adherence between the clot and the vessel wall, so that it is not readily released. The rarity of death from pulmonary embolism in the hundreds of thousands of injections for varicose veins is an additional proof of this contention. Here a deliberate effort is made to induce damage to the vessel wall and incite the formation of a clot, and the procedure is rarely followed by pulmonary embolism. In our group there had been no varicose veins injected, and there were only thirteen cases in which varicose veins were described.

MECHANICAL VENOUS COMPRESSION

In attempting to find a cause for the initial thrombus acting as a source for pulmonary emboli, we considered the question of mechanical venous compression, chiefly from tumor. We found definite evidence of such pressure in twelve patients, and felt that such a factor might have played a part in eleven more. There were several instances in which large pelvic tumors, generally of the uterus, could have produced pressure upon the veins within the pelvis. In the traumatic series of nineteen cases, casts had been applied to the lower extremities in six. In one case the cast was so tight as to cause considerable swelling of the foot and had to be removed. Death occurred suddenly two days later, and at postmortem examination thrombosis of the veins of the leg was described with multiple pulmonary emboli.

OTHER FACTORS

Obesity was mentioned thirty-five times, emaciation thirty, a decubitus ulcer was present in sixteen, and a malignant tumor was evident in thirty-four. Some form of prolonged debilitating illness preceded death in thirty-seven instances, twenty-eight of these being in the medical group. These were mostly far-advanced malignancy and also cerebral pathology, cord changes, psychoses, extra-pulmonary tuberculosis, severe pernicious anemia, and pellagra. They were all bedridden for long periods, more or less emaciated and dehydrated. It was believed that no definite conclusion could be drawn from these observations, although dehydration and impairment of circulation may have influenced thrombosis.

POSTOPERATIVE SERIES

It is of interest to note that of the sixty-four postoperative deaths there were only thirteen instances in which no etiologic factor other than the surgery could be discovered. The other cases gave evidence of suppuration, cardiac disease, acute phlebitis, sepsis, indication of prolonged venous compression or debilitating illness—factors which, in the nonoperative series, we found to be capable of producing thrombosis without surgical intervention. This observation emphasizes the importance of excluding various other sources of pulmonary emboli before attributing a postoperative attack solely to the surgical procedure. In only four cases, two of hysterectomy, one of hemorrhoidectomy, and one of herniotomy, were thrombosed veins found in the region of the operation.

SITES OF THE EMBOLI

The thrombus responsible for the embolus was found in 122 cases. Of this group the largest number, fifty-four, was found in the pelvic veins including the iliacs, the veins of the broad ligaments, and the periprostatic and perivesicular plexuses. Thirty-one cases of thrombosis of the various veins of the lower extremities were described. In twenty-three instances, emboli apparently arose from clots within the right auricle, and in three cases the probable source was a mural thrombus in the right ventricle. Many of the emboli of undetermined origin must have come from the legs, as these veins were rarely explored except where there was clinical evidence of thrombosis in the legs.

COMMENT

A review of this series of figures points to certain conclusions which we believe are of importance. The largest number of pulmonary emboli occur in medical rather than postoperative patients. In the vast majority of cases there is some predisposing factor which explains the appearance of venous thrombosis. Heart disease, with accompanying decompensation and congestive failure, is probably the most frequent of such factors. The most apparent mechanism of production of the venous thrombi in cardiac failure is the slowing of the venous current. This is well illustrated by the frequency of thrombi within the auricles in auricular fibrillation. A similar mechanism probably explains the thrombi produced by pressure upon the veins by tumors, casts, or bandages. Impaired venous circulation may also be produced by prolonged muscular inactivity and diminished respiration. Such conditions exist in any bedridden patient, and particularly in postoperative patients who have undergone any form of abdominal surgery. Venous slowing from lack of muscular action gives a reasonable explanation for the pronounced frequency of thrombosis in the veins of the lower extremity, where muscular activity is at a minimum, as compared with the rarity of thrombi in the arms which are frequently in motion and often elevated, even in a bedridden patient.

TRAUMATIC CASES

It seems significant that of the nineteen traumatic cases, fifteen were fractures of the lower extremities and three were fractures of the ribs. In the only other case there was a fractured skull, sinus thrombosis, and an infected embolus. There were five cases in the group with severe heart damage, and casts had been applied in six other instances. There were no cases of trauma to tissues without the fracture of a bone, which required a prolonged period of immobilization. The average length of time between the accident and the occurrence of the embolus was seventeen days. The fractured ribs undoubtedly resulted in depressed respiration. It would seem that venous stasis from cardiac disease, casts, depressed respiration, and muscular inactivity may also have been an important predisposing cause of venous thrombosis in the traumatic group.

Fig. 2.—Serial electrocardiogram. The first taken four hours after a severe attack of pulmonary embolism and twenty-four hours after a mild attack. Lead IV taken with left arm lead over apex.

THROMBI

Unfortunately, the most dangerous type of venous thrombosis, from the standpoint of the likelihood of emboli, appears in those cases where the thrombosis is of the bland and noninfected type. Such patients give little or no indication of their condition, and the sudden appearance of a pulmonary embolus may be the first suggestion of an unrecognized thrombus. Where an actual inflammation of the intima of the veins develops, as in an acute thrombophlebitis, with accompanying swelling, redness and tenderness, there is not so great a hazard of the liberation of an embolus.

SIGNS AND SYMPTOMS OF EMBOLI

Although pulmonary emboli of large size are often fatal, there are probably many more instances where such is not the case. There is a great variation in the clinical picture produced, dependent upon the size of the artery occluded. When the embolus obstructs the main pulmonary artery, or one of its major branches, death may be instantaneous. If not, the patient suddenly presents the picture of extreme anxiety. He sits up in bed with rapid, shallow respiration and fights for breath. There is usually no severe pain, but a marked sense of substernal oppression and often a fear of impending death. The skin is pale, cold and wet with sweat. Cyanosis is usually present, which may be moderate or extreme. The pulse is rapid, small, and frequently disappears completely. Arterial blood pressure falls and venous pressure rises, so that distention of the cervical veins is usual and should be sought in every case. On auscultation the heart sounds are faint and rapid. An intensification of the pulmonary second sound is quite consistently present. This is a valuable sign and is often accompanied by a visible pulsation in the left second intercostal space close to the sternum. A to-and-fro friction rub may be heard in this area. If the patient survives the immediate attack, signs of right heart failure may gradually develop with increased venous distention, enlarged liver, and anasarca.

* Summary of statistical data more fully described in text.

The result depends to some extent upon the previous state of the cardiac reserve. There may be temporary improvement, followed by another immediately fatal embolus. Even the most severe attack, if not immediately fatal, may after a day or two show signs of improvement and be followed by complete recovery.

Emboli of smaller size will produce a much less dramatic and characteristic picture without the evidence of shock described above. There may be no more than a sudden increase in the respiratory rate, with slight substernal discomfort. The pulse suddenly quickens and there may be a slight cough. Later there may be depressed breath sounds, moderate dullness and a few râles in the lung. Hemoptysis is frequently present, but this may not appear for a day or two. There is often a sharp sticking pain in the chest on respiration; fever and a moderate leukocytosis usually appear. With these small emboli the signs of so-called cor pulmonale, described above, may be entirely absent. Such a picture occurring in a postoperative patient may raise the question of pneumonia or atelectasis. The suddenness of the onset and the lack of more definite physical signs would rather suggest an embolic accident. However, the presence of a large area of infarction may give all the signs of consolidation. Hemoptysis is not a constant feature, and when present is apt to appear some hours or days after the initial attack. It is more usual with cases of impaired circulation and congestive failure. The pain in the chest increased by deep breathing is produced by pleural involvement when the infarcted area reaches the surface of the lung. It is not always present and is usually absent at the onset. Embolic obstruction of smaller vessels producing few or no symptoms is undoubtedly common. There may be no more than slight and transient dyspnea, moderate pulse acceleration and slight substernal discomfort.

IMPORTANCE OF RECOGNITION OF EMBOLI

Although these minor embolic accidents may produce so few symptoms and signs, they should not be disregarded. Our review of these autopsies has demonstrated how often these emboli are multiple with evidence of previous clots in the pulmonary arteries which appeared at variable times before the fatal embolus. In cardiac patients with heart failure, in medical or surgical cases with suppuration, sepsis or prolonged confinement to bed, in postoperative patients (particularly those involving pelvis or abdominal surgery), one should keep in mind the likelihood of such an accident in connection with any development in the lung or heart. One should search with care for any evidence of venous thrombosis. Such a focus is usually not evident, but if found will substantiate the suspicion of pulmonary embolism. These patients should be watched with unusual care and one cannot overemphasize the necessity of absolute rest and avoidance of any slight exertion, such as straining at stool or urination, getting out of bed too soon, or moving too vigorously in bed. Fatal accidents often occur during such activity. When a pulmonary embolus is suspected, the period of convalescence and bed rest should be prolonged for four to five weeks.

ELECTROCARDIOGRAMS

The three electrocardiograms occurring in this autopsied series, together with a study of seven tracings in patients who have recovered from characteristic attacks of pulmonary embolism, have shown certain valuable diagnostic changes. S₁ is constantly present and usually of considerable amplitude. The S-T interval in both Leads I and II, arises well below the base-line and gradually ascends to the T wave. This may suggest on occasions a diphasic T, but we believe the change is due primarily to the S-T segment rather than to the T

wave itself. Lead IV (Wolferth derivation) shows constant abnormalities in the T wave, which is usually upright rather than downward, but may be diphasic or of abnormally low voltage. The prominent Q_3 mentioned by White was seen six times out of ten. The characteristics described above have been found to be present with a fair degree of regularity. They are of definite value in differentiating the acute cor pulmonale from an attack of coronary occlusion. However, we feel it wise to emphasize that such changes are not uniformly present—particularly in minor attacks—and that the form of the electrocardiogram in every instance must be influenced by preëxisting cardiac pathology.

These patients are usually too ill to be disturbed for roentgenograms. There were several pictures in this series which were of no diagnostic help. However, in one instance a pronounced exaggeration of the pulmonary artery shadow appeared in the cardiac silhouette. Two weeks later this had entirely disappeared. It is logical to expect such a change in the pulmonary artery if a major portion of the pulmonary arterial circuit has been obstructed. At times a triangular-shaped infarct may be seen in the x-ray film.

PULMONARY EMBOLISM AND CORONARY OCCLUSION

It may be well to emphasize the similarity and also distinguishing features between pulmonary embolism and coronary occlusion. In both instances the patient presents the picture of shock and collapse, with extreme dyspnea, orthopnea, and sweating. Coronary occlusion is apt to cause more severe pain with radiation to the arm, and pulmonary embolism is apt to cause more cyanosis. Accentuation of the pulmonary second sound and occasionally a pulsation or friction rub in this area are most important points, indicating a pulmonary embolus rather than a coronary accident. Pulsation of the cervical veins, pain on respiration, jaundice, and hemoptysis, are more frequent following pulmonary embolism. A previous history of angina pectoris would suggest coronary occlusion, while congestive failure, prolonged bed rest, or signs of venous thrombosis would favor embolism. Electrocardiograph changes may occur in both conditions, but usually present distinguishing features.

Other conditions which may prove confusing are spontaneous pneumothorax, dissecting aneurysm, pneumonia, pulmonary atelectasis and acute upper abdominal accidents, as perforating peptic ulcer. These should be relatively easy to differentiate, with an adequate history and careful physical examination.

PREVENTIVE THERAPY

Prophylaxis is more important than treatment. Keeping in mind the various predisposing factors to venous thrombosis, one should make every attempt to prevent such conditions. Patients should not undergo elective operations with any degree of cardiac decompensation. Those who must face emergency surgery while showing circulatory failure should have careful postoperative care under

competent medical supervision. Surgeons should be careful to avoid undue trauma to veins, particularly in pelvic and hernia operations. Casts and bandages should not be applied tightly enough to cause venous obstruction. With thrombophlebitis localized in the saphenous vein, ligation of the vessel above the thrombus deserves consideration. As venous stasis is probably the greatest single factor inducing venous thrombosis, every effort should be made to prevent its occurrence. Frequent change of position, elevation of the foot of the bed, muscular activity of the legs and massage have all been recommended. Systematic exercises of the extremities for all postoperative patients were advocated by Richardson in 1904, and various contrivances have been used for this purpose. The routine postoperative use of carbon dioxide to stimulate respiration should also be of value in preventing venous stagnation. Unfortunately, however, it is impossible to prevent the occurrence of cardiac disease and decompensation, as well as the development of suppurative conditions—particularly abdominal. These two important causes of venous thrombosis will always be responsible for a certain number of pulmonary emboli. Some of the procedures which have just been mentioned, although employed to prevent venous stasis and thrombosis, have the disadvantage of aiding liberation of clots from thrombi which have already formed and which may have been undetected. With any suspicion of such an event, all attempts to promote circulatory activity should be stopped at once. Enforcement of complete rest after the appearance of a small embolus cannot be too strict. Such a regimen may prevent the liberation of a larger and fatal embolus.

TREATMENT

Treatment for the immediate attack does not differ greatly from that employed in coronary occlusion. Complete and prolonged rest in bed must be maintained. The patient will be more comfortable with elevation of the head and shoulders. There is no indication for digitalis. Morphine should be used for restlessness and discomfort. Oxygen is of great value in the presence of cyanosis or air hunger.

A few lives have undoubtedly been saved by the use of the Trendelenburg operation, which consists in removing the embolus from the pulmonary artery. It requires the presence of a trained and equipped operating team at the patient's side the moment the operation happens to be indicated. This may be practical in some large hospitals. It is complicated by diagnostic, prognostic and technical difficulties which will probably prevent its widespread use.

IN CONCLUSION

In conclusion, we would like to emphasize four points. Pulmonary emboli are frequently seen in both medical and surgical patients. They may be confused with coronary occlusion, pneumonia, atelectasis, and other conditions. The emboli are characteristically multiple and recurrent. It is important to remember them in the differential diagnosis of many acute pulmonary and cardiac con-

ditions, and to diagnose the small emboli in order to take the proper steps to prevent a recurrent and fatal embolus.

1136 West Sixth Street.

DISCUSSION

DONALD J. FRICK, M. D. (1136 West Sixth Street, Los Angeles).—This is an excellent and timely review of present knowledge concerning pulmonary embolism. The statistics from both the General Hospital and the Children's Hospital are of extreme value in pointing out an important factor in the production of emboli, *i. e.*, slowing of the blood current. Children, during their illnesses, move about. Their circulation is usually at an optimum. Their heart muscles are competent. As age advances, we have the degenerative changes of the heart muscle, which slow the blood flow both in the periods of shock and mobilization during medical and surgical illnesses.

The realization of the danger of even moderate cardiac damage, plus temporary immobilization of portions of the body, especially the pelvis and the lower limbs, will make us more careful in the handling of all our patients—seeing that the heart is improved to its optimum and passive or active motion of the extremities is made a routine. Thrombi form as a result of retarded blood flow. From thrombi come emboli.

Early diagnosis is a necessity, both from the standpoint of proper treatment and the prevention of later emboli. This point is well brought out, and should at all times be kept in mind in the cure of this hazardous accident.

Every physician, whatever his trend, should have the fullness of knowledge regarding pulmonary embolism, its diagnosis, prevention, and treatment. This emergency will come to all of us, and only by full knowledge can we save lives.

✽

ROY E. THOMAS, M. D. (1136 West Sixth Street, Los Angeles).—In this paper by Doctors Ware and Bullock, the importance of pulmonary embolism to both surgeon and internist is indicated in the very first paragraph. Any condition which, in a five-year period, is responsible for nearly 250 deaths in a single hospital, deserves most serious consideration.

Most of us, I fear, have been accustomed to consider pulmonary embolism a sequel to some surgical procedure or trauma. The authors show that surgery is responsible for less than one-half the cases in their series, and in the majority of these there was the additional factor of suppurative.

I can add nothing to the preventive measures advocated in the paper, but I would emphasize the importance of avoiding elective surgery in patients past middle life who are known to have impaired circulation. Also, in those cases of thrombosis of the saphenous vein, resulting from trauma or infection, we can urge the ligation of the vein in the groin. These cases are not common, but fatal embolism does occasionally occur when the free end of the snake-like thrombus, which has been waving in the blood stream, breaks off.

Once embolism occurs, the outcome usually depends on the size and location of the blocked vessel and the previous condition of the patient. In addition to the therapeutic measures advocated by the authors, perhaps the immediate intravenous use of papaverin deserves mention. This treatment was advocated by Pal in 1914. If it be true that the point of lodgement of an embolus depends on spasm of the arterial wall rather than on the diameter of the vessel relative to the size of the embolus, then the use of a quickly acting antispasmodic drug such as papaverin is certainly rational. Collins has recently reported a series of ten cases so treated, with only one fatality. This would be encouraging, indeed, if one could be sure that the diagnosis of pulmonary embolism was correct in every case.

In this connection the following case is of interest. A patient was operated upon at the Los Angeles General Hospital for perforated duodenal ulcer. Several days later, while apparently convalescing, he suddenly went into shock, with all the signs of pulmonary embolism. He was given papaverin, grain one, intravenously, with prompt and striking improvement. A few days later an apparently identical attack occurred, which failed to respond

to the same treatment. Autopsy showed no evidence of pulmonary embolism or other pathology to explain the sudden death.

Recently, a patient on one of the medical wards was allowed out of bed for the first time following lobar pneumonia. He walked a few steps and collapsed, with all the classical symptoms of pulmonary embolism. At the autopsy no embolism was found.

I cannot close this discussion without a word of condemnation for the Trendelenburg operation. I quote Evarts Graham: "When one considers the chance of error in wrongly interpreting the symptoms, and, therefore, in making an erroneous diagnosis of pulmonary embolism, the possible enthusiasm for the operation necessarily wanes. Still more must one's enthusiasm diminish when it is considered that not only is it necessary to establish a diagnosis of pulmonary embolism, but also to determine that in the particular case the embolism will prove fatal unless the operation is performed. Every surgeon of large experience has occasionally seen patients recover spontaneously in cases of embolism which seemed at the outset as if they would be fatal. After all, the operation is a very serious procedure. Considering these facts, one cannot help wondering whether, if it gains popularity, more patients will not die from the operation than would die from pulmonary embolism alone."

✽

PHILIP H. PIERSON, M. D. (490 Post Street, San Francisco).—Doctors Ware and Bullock have made a very thorough survey of the question of pulmonary embolism and have supplemented this study with a careful investigation of considerable autopsy material.

There are two points which I would like to emphasize: first, sterile emboli often go into normal lungs without any complications save for a transient spike of fever and local congestion, which quickly clear. On the other hand, when a sterile embolus is lodged in a congested or infected portion of the pulmonary field, trouble generally develops. I think a great many small, sterile emboli lodge in the lung, and we have no knowledge of their occurrence.

The second point that I would like to add is that, after a lung has been compressed for some time by fluid, small thrombi often form in the pulmonary vessels. If a large amount of this fluid is evacuated at one time, in these long-standing cases, emboli are at times set free and either cerebral or visceral damage takes place. It is safer then, in long-standing fluids, to take off not more than 500 to 700 cubic centimeters at a time.

PSYCHOSIS IN THE MENTALLY DEFECTIVE*

By F. O. BUTLER, M.D.
Eldridge

DISCUSSION by Ruggles A. Cushman, M.D., Talmage; Edward W. Twitchell, M.D., San Francisco.

PSYCHOSIS is a much more frequent complication of mental deficiency than is generally believed. Frequently a patient, who comes to the attention of the court or the doctor because of peculiar actions or inability to adjust in the community, is given a mental test, and when found to be subnormal is dismissed as feeble-minded and all his symptoms ascribed to this condition, while in reality he may also be suffering from a psychosis, and it is the psychosis that is causing his inability to adjust. He may have been getting along well enough until his mental upset occurred. This patient needs the care afforded by a mental hospital. If he is returned home his difficulties

* From the office of the Medical Director, Sonoma State Home.

Read before the Neuropsychiatry Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

continue, while if he be sent to an institution for mental defectives or to a boarding school he will not fit in with other defectives and will continue to be a problem until he finally is sent to a mental hospital or recovers from his psychosis.

LIMITATIONS OF INSTITUTIONS FOR THE MENTALLY DEFECTIVE

Institutions for the mentally defective are not equipped to care for psychotic aments. The majority of the patients at such institutions require custodial care and training from which the disturbed patients cannot benefit because of their mental condition; while their behavior taxes the facilities of the institution in caring for them and disturbs the routine of the ward on which they are placed. These patients frequently keep those otherwise well behaved in an uproar, and are unsatisfactorily treated because the attendants are not usually trained in the care of psychotic patients.

DETERMINATION OF THE MENTAL STATUS IMPORTANT

Therefore, in order that our state and private institutions may function at their best, care should be taken to ascertain the exact mental status of a person before it is decided where he should be sent. Merely because he has a low intelligence quotient does not mean that his chief complaint is mental deficiency.

True, it is difficult to be sure just what ails a patient seen in the detention home, and who can be observed only for a short time before his disposition is decided upon. However, a trained psychiatrist can be fairly sure of his diagnosis, and will avoid many more errors than can a person whose practice encompasses chiefly other fields of medicine. Therefore, it would be well for the judge or person who has the disposition of the case in hand to have a competent man see the patient and give him a chance to observe him and be guided by his recommendation.

With reference to the mental rating arrived at by a psychometric reading, it must be remembered that a person with normal mentality will, when acutely disturbed, or when the condition is due to deteriorating mental disease, test in the feeble-minded group. While his intelligence quotient fits in this group, still he should not be treated with that group because his intelligence quotient is the result of, and not the cause of, his trouble.

TWO STATE INSTITUTIONS FOR THE MENTALLY DEFICIENT IN CALIFORNIA

There are two state institutions for the mentally deficient in California—one situated in northern California, at Eldridge, which was established in 1887 in another part of the state, and which on April 1, 1936, had an actual population of 2,630, representing an overcrowding of 21 per cent. The other state institution is situated in the southern part of the state, at Pacific Colony, and on April 1, 1936, had an actual population of 734, representing an overcrowding of 18 per cent. The total population of the two institutions on this date was 3,364. Also, there is a long list of over 2,000 patients awaiting commitment to these two insti-

tutions, and there are numerous private homes for the care of such children, while many are cared for in their own or foster homes.

THREE MAJOR GROUPS OF PATIENTS

The great majority of these patients may be divided into three large groups:

The obviously defective, who for one reason or another cannot be cared for in their community;

The epileptics;

And the defective delinquents who are sent here rather than to prison or correctional school.

Forming a fourth much smaller group, but still large and troublesome enough so that they are demanding ever-increasing attention, are the psychotic aments with a problem all their own. Because they are psychotic they do not belong among the stable and adjusted feeble-minded, nor, because of their basic deficiency and frequently their age, do they belong among the adult group cared for in state hospitals. A special institution for their care is a pressing necessity, which we hope will be met in the near future.

Aments fall heir to the same psychoses found among the general population. Due to their short-life expectancy, emphasis is placed on those psychoses prone to occur in adolescence and early adult life. Also these patients are subject to many transient periods of mental upset which cannot be readily classified, and which are accordingly labeled psychoses associated with mental deficiency. While all the recognized types of psychoses occur in aments, their symptoms and signs are frequently considerably altered because of the associated deficiency. However, the same etiologic factors and symptomatology are in evidence here as they are among mental patients who are not defective.

DIAGNOSIS OF TYPES OF MENTAL DISORDER

Diagnosis of the type of mental disorder is complicated by the degree of defect present. In the lower grades, only actions are available as guides to what is the condition of the mind, as the patient is very frequently unable to give the examiner information in any other way. Thus, it is largely a matter of clinical judgment as to what type of psychosis is present. The higher the intelligence quotient, of course, the more nearly the problem approaches that found in the normal population.

As to whether the patient has a definite major psychosis grafted upon his amentia, or whether it is merely a minor psychotic episode associated with the deficiency, depends upon the character of the behavior and the duration of the upset. Many of the feeble-minded have transient periods of psychic upheaval, varying from mere temper tantrums to definite psychotic episodes of short duration or to definite major psychoses.

Because of the peculiar actions of the idiot and imbecile, and the childish behavior of the morons, it is sometimes very difficult to say whether his behavior is normal for him or if he is suffering from a psychosis.

SURVEY OF THE PSYCHOSES AT SONOMA STATE HOME: JANUARY, 1930, TO JANUARY, 1936

A survey of the psychoses that have occurred at the Sonoma State Home from January, 1930, to January, 1936, shows that almost every type of psychosis tabulated by the American Psychiatric Association is there represented.

ENCEPHALITIS SEQUELAE

Of chief interest, because it is a most recent development, is the large number of cases which are the result of encephalitis with personality changes in the individual. These patients very frequently are normal until they have lethargic encephalitis, influenza, or some childhood disease. After recovery they become quite different people and are profound behavior problems. These patients undoubtedly have organic brain damage, but so far there has been very little material available for study. Their intelligence quotients remain high, but their emotions are profoundly altered. While these patients are not feeble-minded, because of their age group—usually under twenty—they are found more and more frequently in our institution because there is no place else to care for them.

Such cases are diagnosed chiefly on the behavior, which includes usually lying, stealing, sex delinquencies, extreme cruelty, resentment of all authority, total disregard of punishment, a complete candor in recounting their behavior with an emotional reaction of complete indifference and a total inability to explain why they act as they do. The history is sometimes barren of evidence of just when the encephalitis occurred. Also the neurologic evidence is usually slight and characterized by the spotty distribution of the lesions. The most familiar sequela of encephalitis, Parkinson's syndrome, is not usually found in this group. We believe that many cases placed in other classifications, especially that of psychopathic personality, really belong in this group and that these cases will assume an ever-increasing medical problem.

From January 1, 1930, to January 1, 1936, a period of six years, there have been 510 patients referred to our psychiatrist because of peculiar behavior noted in the institution. Of these cases, 287 have been found to be suffering from some form of psychosis.

PSYCHOSES BY GROUPS

1. The commonest psychoses were found to be those associated with epilepsy. As the institutions caring for the mentally deficient are the only institutions in the state caring for nonpsychotic epileptics, a large part (approximately 25 per cent) of our population is made up of these unfortunate sufferers. It is only to be expected that a group suffering from this profound nervous disorder would develop a considerable number of psychotics. The commonest mental picture is that of deterioration, a gradual development of mental dullness, slowness of association and thinking, impairment of memory, irritability, or apathy. Various accessory symptoms, paranoid delusions

and hallucinations, may be added to this fundamental deterioration. These patients are the slow-moving, thick-speaking, irritable individuals, frequently seen. They do not present much of a problem unless their hallucinations and delusions lead them to attack their fellows, when they must be segregated.

The second type of epileptic psychoses, the epileptic clouded states, is characterized preceding or following convulsive attacks by dazed reactions with deep confusion, bewilderment and anxiety or excitement, with hallucinations, fears and violent outbreaks. These are the dangerous type as, during their confused periods, they do many impulsive acts that frequently cause injury to others, and of which the patient is wholly unconscious and for which he develops a complete amnesia.

Other epileptic types of psychoses show paranoid trends, hallucinatory states, depressions, elations, and manic attacks, with few other manifestations.

The prognosis in these cases is, of course, grave. They continue steadily downhill; and, while the psychotic episodes may be brief, they tend to recur and be prolonged.

The epileptic psychoses comprised 24 per cent or almost one-fourth of our psychotic patients.

2. The next commonest group are the dementia praecoxes, which comprised 17 per cent of our psychoses. While it is difficult to differentiate between the brief upsets frequently met with in defectives and a true dementia praecox psychosis, true schizophrenia does occur in defectives, even in the lower types where it might be thought it would not occur. In fact, when first seen, it is often hard to be sure whether the patient is primarily defective or if he has always been a praecox and has been sent to us on the basis of a low intelligence quotient due to deterioration or pre-occupation resulting from the psychosis.

The various types occurred in the following frequencies: simple, three cases; hebephrenic, forty-two cases; paranoid, two cases; catatonic, two; unclassified, two. The only difference between these cases and those met with in mental hospitals is that the patients are more inaccessible and do not show the strikingly bizarre features so frequently seen. They are more frequently characterized by and diagnosed on their typical behavior so rich in mannerisms with evidences of hallucinations. Aside from the paranoid types they do not present a serious problem, as they are much better workers than the purely defective and fit in very well.

3. The third largest group includes those called psychoses associated with mental deficiency. These are usually of an acute transitory nature and most commonly have episodes of excitement with depression, paranoid trends, and hallucinatory attacks. The attacks are brief, frequently being readily brought on by minor events in their environment, and are usually readily controlled. They may be likened to the temperamental outbursts of the spoiled child, but are more deep-seated. These comprise 16 per cent of our cases.

4. The fourth group are those best grouped under the heading of behavior disorders. Our institution receives a large number of defective delinquents, many of which are found to have a definite organic basis for their behavior. They compromise 10 per cent of our series. They are caused by encephalitis, either the lethargic type or that associated with childhood diseases. In some cases, even though there is no history, the behavior is so typical that they are grouped here. Causes of these thirty-two behavior problems were as follows: lethargic encephalitis, measles, influenza, pneumonia, and pertussis. Patients presenting the typical Parkinsonian picture occasionally have associated behavior disorders, and also become frankly psychotic. The commonest psychosis in this latter group is a psychoneurosis. However, depressions and melancholias are also found. Evidence of deterioration also occur in a few cases.

This group presents a serious problem in their care and training, as discussed elsewhere.

5. The fifth group is that of the manic depressive psychoses, which comprise 6 per cent of our series. This psychosis occurs in the higher groups and more frequently are represented by the manic phase than by the depressed phase.

This group is a complete misfit in our set-up, and must be segregated early to avoid damage to themselves and to others.

6. The sixth group is that of the psychoneuroses, comprising 5 per cent of our series. They represent the usual features and occur among the higher grades of our patients, as would be expected. They are serious problems and cannot be well cared for here.

Psychopathic personalities comprised 5 per cent of our cases, and of these only one-fourth had periods of upset which placed them as definitely psychotic, while the rest were made up of sexual pervers and emotional abnormalities.

SYPHILITIC AND ALCOHOLIC FACTORS

Syphilis played a part in only 4 per cent of our psychoses, and of these only one-third were juvenile paretics. Trauma accounted for 2 per cent of our cases, three cases showing post-traumatic personality disorders and two cases showing post-traumatic mental deterioration. Psychoses were associated with somatic disease (tuberculosis) in two cases, and there was one case of senile psychosis developing in an old defective who had spent the greater part of her life in our institution.

Among the psychoses we did not see were the alcoholic psychoses and the involutional melancholias. Alcoholism plays a minor rôle in the lives of our patients as we see them. Their drinking habits are due to the effect of their environment on their mentality, and alcoholism is only an incidental feature, seemingly taking no deep hold upon them.

The intelligence of this entire group of 287 cases by psychometric examinations showed a range from the idiot to the normal, as per our psychologist's report in his routine examinations on admission and some on reëxamination, as indicated.

GENERAL CLASSIFICATION

The following were the general classifications as we group them with the range and average intelligence quotient:

TABLE 1.—General Classifications With Range and Average Intelligence Quotients		
	Range	Average
Psychopathic personalities	52-89	70
Lues	49-57	53
Psychoneurosis	73-90	80
Dementia praecox	26-70	60
Manics	20-72	45
Epileptics	41-94	70
Behavior disorders	41-90	70
Psychosis associated with mental deficiency	9-70	60

Thus indicating that mental disease may be expected in any degrees of mentality, and the lower the mentality the more difficult it is to make a differential diagnosis.

TREATMENT

In general, the treatment of psychotic aments is the same as that for other psychotic patients. However, there are one or two points that I would like to stress:

First: Since the mentally defective is, on the whole, a young group, many or most of the psychoses occur in patients under twenty. For this reason, as well as the fact that any degree of amentia may be present, they are rendered misfits in mental hospitals. There should be a special ward or wards attached to mental hospitals where these patients could be cared for, and in which they could be properly segregated. When this step is taken, we will have solved, in a considerable measure, the problem of the care and treatment of these patients.

Second: The rapidly growing group of personality changes following encephalitis do not, at present, fit anywhere in our scheme of treatment. They are not psychotic in the way that most mental hospital patients are, and they are usually not yet adults and thus do not fit in the institutions for adults. Also, they are not necessarily feeble, often having a high intelligence quotient, and thus they do not fit with the regular defective type. Again, they are such behavior problems that they are difficult to care for in an institution for mentally defective patients. The pressing need at the present time in California is a group of wards devoted to the care, according to their age group, of these postencephalitic patients.

The treatment of these patients is, as yet, only in the experimental stage. There are several clinics in this country working with these patients, and, while a few cases appear to recover and adjust satisfactorily, there is always a chance that these are only temporary cures, since many patients will do well for a few months, usually about six, and then return to their former behavior. This seems to be due to their inability for sustained interest in their environment and activities. The main plan of attack is one in which the child is removed from his home environment and placed

in a special school with twenty-four-hour supervision, with a strict regular routine and frequent changes of activity throughout the day. These children are naturally nonconformist and must be made to conform; but the method by which this can be done varies in each case. Punishment, as such, has little effect and should be discarded. In their homes these patients have been the subject of much undesirable personal attention because of their behavior, and have been singled out from the rest of the family. The bad effects that this treatment has had on the child must be overcome.

DISPOSITION OF THE PATIENTS AT SONOMA STATE HOME

The disposition of these patients up to this time might be of interest, as we are all concerned with the end-results of our treatments, whatever they may be.

TABLE 2.—Disposition of the Patients at the Sonoma State Home

	Per Cent
Transferred to other institutions	48
Retained (due to psychosis being mild, or where we feel their deficiency predominates over their psychosis)	49
Transferred and returned, as recovered from their psychosis or greatly improved and their deficiency only remains or at least predominates over their psychosis	1.3
Paroled	1.2
Died	0.5

This group have little or no sense of right and wrong, and do many impulsive things that result in harm to others. For this reason they should be segregated indefinitely until it can be ascertained that their antisocial tendencies have been curbed. Also, they need routine schooling. They are so regularly excluded from school that schooling must be provided in a special class and institution, for the facilities for the proper care of these patients and the psychotic defectives in California have yet to be provided.

Sonoma State Home.

DISCUSSION

RUGGLES A. CUSHMAN, M. D. (Mendocino State Hospital, Talmage).—We who are attempting to care for psychotic patients in the State hospitals are intensely interested in the problems of mentally defectives. While we do receive those mentally defective patients who are transferred from the homes for the feeble-minded, correction schools, etc., all psychotic patients we receive from the various counties, if they are not already mentally defective, soon lapse into that condition, after more or less of an interval, as a result of their mental storm. This defect in their mentality is almost invariably continuous. With some, of course, the advance is slow; so that after patients with this psychosis have sunk to a certain level they remain practically the same, with a more or less modified deterioration as the years go by.

Every one of these psychotic patients, after one such mental storm, never completely resumes his former mental powers. Owing to the inability of the relatives or friends of the patients to provide suitable homes, they become wards of the State. The reader may be interested in knowing that at the present time we have approximately 25,000 of these wards scattered throughout mental hospitals, homes for the feeble-minded, correction schools, etc. Quite a proportion of these patients have been under the care of the State for many years. For instance, here at Mendocino we have seven patients who have lived in this

hospital between forty and fifty years. We have approximately twenty-five who have lived here from thirty to forty years. The probability is that our average time for residence in this hospital with all patients is approximately ten years.

This all involves a tremendous expenditure on the part of the State, as, with the practice of the utmost economy, we are compelled to spend around \$225 each year per capita. In other words, the Legislature appropriates each session for the support of State hospitals for the biennium approximately \$14,000,000.

It may also interest the reader to know that the sum total of admission for all State hospitals represents a turnover of approximately one thousand patients per month. The admission of new patients and the return of old patients from parole is approximately one thousand; the discharge and parole and deaths amount to around nine hundred, leaving a surplus of about one hundred scattered throughout the various State institutions. This means that there is a steady increase in California of around one thousand patients each year who have to be provided with a suitable home and proper maintenance. This condition has caused excessive overcrowding. None of the institutions have sufficient bed capacity to care for their inmate population, making it necessary in each hospital to have some patients sleep on the floor. Up to the present time it has not been possible to overtake this excess by the erection of new buildings, so that one may readily see the problem confronting all those interested in the proper care of these State charges.

We who are engaged in State work are trying to place these psychotic and defective patients in such a bodily and mental condition that they will be capable of adapting themselves to their surroundings and conforming in action to the usages of society in so far as may be possible.

You will realize from the above that I have viewed this subject, not so much about psychoses developing in the mental defective, as I have the defectives who run along with our psychotic condition. We are aiming to get these patients out at the earliest possible date, back to homes and relatives, with a different view of life as will cause them to have less conflict in their contact with other people, even though they may be fundamentally in the mentally defective class.

✱

EDWARD W. TWITCHELL, M. D. (909 Hyde Street, San Francisco).—It may no doubt surprise some to learn from Doctor Butler's paper that the mentally defective may become insane. But a moment's reflection should show that just as the stupid normal may become insane, so may those who are even more stupid, and that, as a matter of fact, no degree of stupidity protects one from insanity. But the lower one goes in the mental scale the more difficult may it become to determine when the feeble-minded become insane, while a feeble-minded patient who has been docile and manageable may, by reason of a psychosis, be converted into one who is far from manageable.

Under such conditions these patients naturally add to the difficulties already great enough in dealing with mental defectives, and some way must be devised for segregating them, otherwise an entire group of inmates under good control may get out of hand. The only thing to do is to place them in a separate ward or in an institution for the insane. Now, a home for feeble-minded, not being designed for the treatment of the insane, has added responsibilities placed upon it which should be avoided if possible.

In hospitals for the insane, one of the difficulties is that so many of these patients being children, they cannot well be put in wards with adults. It is not likely that the idea of a separate institution for psychotic aments would find favor in these days when there is so much difficulty in providing funds for institutions already existing.

The most practical way out would undoubtedly be to set aside wards for psychotic aments in the State hospitals for the insane. The epileptic who becomes psychotic is always a particularly difficult problem by reason of the tendency to do violent things, and some terrible things have been done by epileptics in a postconvulsional haze. The encephalitics with character change began to show themselves as a problem soon after the great epidemic. They were especially not easy on account of the fact that

they were at times so apparently normal and it was hard to convince their relatives and friends that there was anything wrong with them.

As Doctor Butler has shown, practically all types of mental disease can be found among the mentally defective, and treatment will follow the same line. It seems to be generally admitted that the juvenile paretics fail to respond to pyretotherapy as well as do the adults.

It is well that a situation already common knowledge to those in the institutional world should be brought to the notice of the profession in general.

TRANSURETHRAL RESECTION: DOES IT REQUIRE AS EXACTING A PREOPERATIVE PREPARATION AS PROSTATECTOMY?*

By H. C. BUMPUS, JR., M.D.

AND

BEN D. MASSEY, M.D.
Pasadena

DISCUSSION by H. A. R. Kreutzmann, M. D., San Francisco; A. M. Meads, M. D., Oakland; J. C. Negley, M. D., Los Angeles.

THROUGHOUT the development of prostatic surgery, overemphasis of some particular type of operation or of some special phase in the preparation or the after-care of the patient, has characterized discussions of the subject. The pioneer surgeons earnestly debated the relative merits of partial and complete enucleation. The next generation heatedly argued the advantages and disadvantages of perineal or suprapubic prostatectomy. Today we are involved in acrimonious discussion of a still newer method of treatment. Such divergence of opinion is indicative of a healthy situation. For, when once all are in agreement upon any subject, progress is likely to cease.

THEORY

At the turn of the past century the techniques of prostatectomy were as numerous as the surgeons who attempted it, and results were extremely unsatisfactory, mortality running as high as 90 per cent. Improvement in this situation was brought about by recognition of the importance of preoperative treatment. The main factors contributing to this improvement were: (1) The practice of preliminary drainage; (2) the development and application of tests of renal function; and (3) a realization of the importance of the control of infection.

The exact time when the importance of preliminary drainage was first recognized is not known, but in the initial volume of the *St. Paul Medical Journal*, dated 1889, Arthur T. Cabot, in an article entitled "Drainage of the Bladder Through a Catheter in the Urethra," wrote as follows:

It is often surprising to see how quickly the character of the urine changes for the better under this treatment. Let us take now an even more serious case, in which the obstruction in the prostate has led to a dilatation of the ureters and pelves of the kidneys. With this condition is usually associated a more or less pronounced degree of interstitial nephritis and consequent interference with the excretory function. The urine under these circumstances

is abundant, but of low specific gravity. An inflammation which starts in the bladder of such a patient quickly extends up the dilated ureters to set up a pyelitis, and if relief is not afforded, the substance of the kidney is presently affected and a pyelonephritis is the result. It may be readily believed that a provision for the constant escape of the urine as fast as it reaches the bladder will do much to hinder or prevent this bacterial extension of the inflammation, and experience justifies this belief."

Consequently the practice of gradually emptying the overdistended bladder naturally gained favor and, in 1903, Guyon advised "to gradually and aseptically empty the overdistended bladder."

Thirty-four years of clinical experience and research have done little but confirm this trite observation so far as the advantages in respect to elimination are concerned. Until there is an unobstructed outlet, it is apparent that fluid intake as well as output must be limited; but once the outlet is rendered constantly open and unobstructed by use of a catheter the intake of fluid can be at once increased, and the better elimination of retained toxic substances can be brought about.

As a result of the definite improvement noted in those having diminished renal function and extensive infection, the idea became gradually fixed that all patients with obstruction at the neck of the bladder, accompanied by residual urine, should receive preoperative drainage of the bladder. This was usually accomplished by an inlying urethral catheter, and the idea became so firmly established in urologic minds that to attempt a prostatectomy without a period of preliminary drainage was looked upon as rank heresy. It was noted, however, that in the extremely debilitated this procedure did not always bring the desired results; and that if one wished to prepare the worst risks for operation it was, on the whole, safer to do a preliminary cystotomy and allow the patient to wait an indefinite period before undertaking the enucleation of the gland. Those who practiced this procedure were accused by their competitors of killing off the bad risks by suprapubic cystostomy and thus not being obliged to report them in their statistics of prostatectomy. However, it became evident to the thoughtful and observant that this method of treatment enlarged considerably the number of cases that were ultimately fit for operation, and Doctor Stevens, in charge of the Bellevue Hospital Urological Service, after adopting it as a routine procedure, lowered the mortality rate of prostatectomy in that hospital by more than 25 per cent. As a result, the two-stage prostatectomy became an accepted procedure for the poorer type of risk.

PRACTICE

It has always been difficult for the authors to understand why a surgical procedure, which is admittedly safer for the poorer risk, is not proportionally safer for the average case. We hear the same line of reasoning today among those who advocate resection for the extremely poor surgical risk, but reserve prostatectomy for the average case. Obviously multiple operations were not popular if a single operation could be made to do the work, and so every effort was made to prepare as many patients as possible by using an in-

* Read before the Urology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

dwelling urethral catheter. However, this method of treatment gave rise to many complications not often emphasized. It had been observed in the two-stage operation that the prospective operative field was kept at complete rest following cystostomy, which in itself was the surest method of reducing infection in that area to a minimum. The prostate also diminished in size, often to such a degree that the amount of tissue obtained at the second operation was disappointing from the standpoint of bulk, and if secondary infection occurred, it usually limited itself to the bladder and did not result in pyelonephritis; but in the case of urethral drainage it was found that many of these patients had a latent prostatitis which became reactivated by the irritation of the urethral catheter. If the patient had an already impaired renal function, such an activated infection sometimes resulted in a pyelonephritis of sufficient severity to throw him into uremia, especially if the catheter became occluded and the bladder overdistended, which frequently occurred if the maximum of nursing care was not exercised. Furthermore, the presence of the catheter in the posterior urethra was often so irritating that instead of the gland diminishing in size as a result of the relief of the obstruction, it actually increased from the secondary engorgement incident to the trauma.

Cabot and Meland reported in 1933 the effect of inlying urethral catheter drainage uncomplicated by extraneous infection. Of seven hundred patients under observation during the years 1926, 1927, and 1928, they excluded all who developed fever when they first came under observation, all who had fever which might have been attributed to a cystoscopic examination, all patients with acute epididymitis, and, finally, all with any pulmonary complications. This reduced the group to 140 patients. On the average, these 140 patients, submitted to inlying urethral catheter drainage, developed within five days a fever lasting seven and one-half days, and sixty-three of these patients showed a decline in renal function as measured by phenolsulphonephthalein.

Theoretically, it may be that such febrile attacks, as reported by Cabot and Meland, result in immunization of the patient against postoperative infection, but practically his hemoglobin is lower, his weight less, his renal function diminished, and his appetite gone. He is, therefore, a greater surgical risk than he was prior to the insertion of the inlying urethral catheter. Such preparation is obviously of doubtful value, no matter what type of surgical treatment is to follow, and should, we believe, be reduced to a minimum. It should never be continued for a prolonged period.

When complete enucleation of the prostate was to follow this method of preparation, the reactivated inflammatory process in the gland was not always of serious moment, for with the removal of the gland *in toto* the original source of the infection was also removed, and the residual inflammation was given adequate drainage facilities through the suprapubic tube.

In the case of transurethral resection, conditions are entirely changed. Instead of being completely removed, only that portion of the gland which is obstructing is resected, and so there is left *in situ* the infected and engorged portion, a potential source of systemic infection and a probable source of immediate ascending infection; for in the case of transurethral resection no adequate drain is available in the form of a suprapubic catheter. If to this regrettable situation is added the fact that the resection has been carried out with a cautery loop which so effectually seals the entire surface for several days that all bacteria and their toxic products are prevented from any possibility of drainage, the wonder is not that these patients have a relatively short hospitalization, but that so many of them escape a generalized urinary sepsis.

This newer conception of the limitations of preliminary preparation leaves a much smaller group requiring any treatment before operation, and logically increases considerably the number of patients having cystostomies. Once the bladder has been opened, many urologists feel it is illogical to perform anything but a suprapubic enucleation as the second stage. If such enucleation carries the same mortality rate that transurethral resection does, this cannot be questioned, but figures do not bear that out. Large series of cases are now on record indicating that a mortality of 6 to 10 per cent is the best that may be expected from suprapubic enucleation, while there are over 5,000 cases recorded of transurethral resections with a mortality of less than 2 per cent. This indicates that transurethral resection, being a procedure of lessened risk, must be applicable to a larger group. In a report of 2,089 cases with prostatic symptoms, Alcock reported 5 per cent to have died without any surgery, showing in figures for the first time what a large group was refused treatment because of the risk of prostatectomy. Where formerly his prostatectomy cases averaged sixty-six years of age, the patients upon whom transurethral resections were performed averaged seventy-three years. The fact that transurethral resection is a less dangerous procedure made this possible, and, being a less dangerous procedure, it can be undertaken in cases where prostatectomy would not be justified. Hence, a preliminary preparation equal to that required for prostatectomy is unnecessary, for the patient need not be in as fine physical condition to survive the safer procedure. Moreover, as we observed earlier in this paper, the essence of all preliminary treatment is drainage or the removal of residual urine by some mechanical means. The accomplishment of this was presumed to result in the gradual improvement of the patient until he reached a sufficiently good physical condition to make operation justifiable.

With transurethral resection the eradication of residual urine is accomplished usually in less than an hour's time, and the patient, emptying his bladder without the aid of mechanical means, will naturally improve more rapidly in the restoration of his renal function and elimination of his infection. This could not have been expected if he were compelled to wear a suprapubic tube or an

indwelling catheter. In other words, the resection replaces the preliminary preparation in a majority of cases.

Since entering private practice eighteen months ago in Pasadena, we have followed this procedure. A review of the seventy-one private cases of prostatic obstruction which we treated by transurethral resection shows that 80 per cent received no preliminary preparation. Thirty-eight per cent of the group was over seventy years of age. The average period of hospitalization was less than one week. There was one death, occurring on the thirty-fifth day following an epididymitis—one of the few cases in which ligation of the vas deferens was not done. While this series is naturally not large, this same trend in the abandonment of preliminary treatment in resection is borne out by the Mayo Clinic figures for last year, when Doctor Thompson and his associates did 765 resections with but seven deaths, 65.7 per cent of the cases receiving no form of preliminary drainage.

In large clinics with well-organized, specially trained nursing staffs, the methods of treatment will of necessity vary from those imposed upon the individual who must work in different hospitals and depend entirely upon routine nursing. Thus, we find that in the Mayo Clinic series but 3.9 per cent of the patients received suprapubic drainage prior to resection during 1935, and Alcock had used it in only thirty of his 1,400 resections, an incidence of 2.1 per cent, while in our private practice we have employed it in 16 per cent of our resections.

In private practice without the help of a specially trained personnel, obstruction of an indwelling urethral catheter may have most serious consequences, not alone in the activation of latent urethral infection and in the production of pyelonephritis, as referred to earlier in this paper, but also in the causation of bleeding following resection. For this reason we believe that a safety valve in the form of a suprapubic tube is invaluable as an assurance of success. The establishment of such drainage we do not make a major surgical procedure, but usually insert the tube through a small suprapubic incision without opening the prevesical space. If treated in this fashion, even patients of advanced age can usually be up and about the following day. Thirteen patients, or 18.1 per cent of our patients, received suprapubic cystostomy. Their average age was seventy-one years. These thirteen patients had an average removal of 26.8 grams of tissue, and total time spent in the hospital for cystostomy and resections averaged twelve and one-half days per patient.

CONCLUSION

The advent of transurethral resection has not only diminished the necessity of preliminary preparation in the majority of cases of hypertrophy of the prostate, but has increased the number of patients for whom the surgical relief is feasible.

112 North Madison Avenue.

DISCUSSION

H. A. R. KREUTZMANN, M. D. (2000 Van Ness Avenue, San Francisco).—There is no question that marked changes in the preoperative care of prostatics have occurred since the introduction of transurethral resection.

It is possible, as Doctors Bumpus and Massey have stated, to operate on some patients with little or no treatment beforehand. The reason is that many come to surgery during the earlier stages of hypertrophy before complications, such as infection, renal damage and general breakdown of the patient, have occurred.

Formerly, these patients were told they had a beginning hypertrophy and were advised to wait until the gland had attained a good size before proceeding to the more formidable operation of either suprapubic or perineal prostatectomy.

We believe that the urologist is justified in removing these smaller obstructions. It saves the patient any future complications; the surgical risk is much less, and there is no need of preoperative preparation, as the authors rightly contend.

Our percentage of immediate operations is not nearly as high as that reported by the authors, as we do not agree that resection replaces the preliminary preparation in a majority of cases. The urethral trauma produced by the resectoscope and the possibility of opening up localized abscesses in the prostate, by the cutting loop, may result in a postoperative cystitis or pyelonephritis. The combination of an acute infection plus operation may produce serious complications, and even cause the death of the patient.

It has also been our experience that an indwelling urethral catheter is not the ideal method of draining the bladder when resection is contemplated. It sets up an irritation, so that bleeding during operation is greatly increased. We prefer, whenever possible, to insert a catheter suprapubically by means of a trocar.

A. M. MEADS, M. D. (251 Moss Avenue, Oakland).—The preoperative preparation of the resectoscopic patient has been more or less a matter of individual opinion, and a free discussion will undoubtedly be helpful. Like many others, I have followed the leader in the treatment of those coming for relief from prostatic obstruction, but of recent years it has gradually dawned upon me that probably the preoperative care in such cases has been overdone. In six individuals, over a period of years, with acute hemorrhage from the prostate, in which the clot-distended bladder demanded an immediate operation without any preparation, a suprapubic prostatectomy was followed by uneventful recovery in five instances, the sixth dying because of self-imposed delay. Meanwhile, we had been noticing that under the long preoperative routine with the indwelling catheter or suprapubic drainage, the treatment was often accompanied by pyuria, temperature, epididymitis, and occasionally fatal pyonephrosis. In many instances these complications must have been due to too much preoperative care, especially where the urine, the renal function and the blood chemistry were normal, when first seen.

There is no doubt that emphasis upon preoperative care has been primarily responsible for reduction in the mortality following all forms of prostatic surgery in the last thirty years; but to apply a rigid routine to all cases, as has been advised by many in the past, has proved to be a mistake which is now being recognized. When one sees, at a large clinic, a patient enter the hospital on Saturday and resectoscoped on the following Monday, one cannot help but wonder if his own long preoperative routine has not only been unnecessary, but harmful. A reflection of this opinion is seen in the recent plea for intermittent catheterization in preoperative care to replace the indwelling catheter. I have always felt that a prostatectomy and a resectoscopic operation were major procedures, and that short cuts in the preoperative care would lead to postoperative difficulties where a long preparation was necessary. I still think that, given two cases equal in every respect, the preoperative preparation for both should be the same, regardless of the type of prostatic surgery decided upon. We study each case, regardless of the methods of operation to be used, individually, and a rational preoperative program is carried out on the basis of the gen-

eral physical condition, blood chemistry, renal function, blood count, cardiovascular condition, etc.

It is difficult to compare statistics of one urologist with those of another. Each one has his own idea as to which case is to be resectoscoped and which is to be relieved by prostatectomy. It is our custom to bring the patient up to his best by preliminary treatment, and then decide—according to the type of obstruction—what procedure should be followed out to give the desired relief.

J. C. NEGLEY, M.D. (527 West Seventh Street, Los Angeles).—In discussion of the paper by Doctors Bumpus and Massey, one cannot help but notice that most of their quoted statistics are from great distances, and from the clinics of so-called enthusiastic resectionists. To properly evaluate any surgical procedure one must not choose the top-notch performers, but take a cross section of the average practitioners and their results. What the public and the profession wish to know is, what is going on in our own locality, particularly so since many of these patients of seventy years or over would never live to reach Rochester or Des Moines. I submit the following tables from Los Angeles and vicinity, making contrast as to surgical procedures, preparation, complications, stay in hospital, mortality, etc., between prostatectomy and resection. I have listed, in Table 1, charity patients, and in Table 2, private patients.

TABLE 1.—*Charity Patients: Comparative Findings*

	Prostatec- tomies, 100	Resections, 100
1. Suprapubic drainage.....	98%	6%
Indwelling catheter, preliminary.....	100%	72%
2. Average days of preparation.....	17	12
3. Prostatitis	57%	35%
4. Fever over 100, chills, preoperative.....	8%	6%
Fever over 100, chills, postoperative.....	21%	29%
5. Complete retention	32%	7%
6. Residual urine over 1½ ounces.....	77%	50%
Urine infected on admission.....	91%	78%
7. Kidney damage.....	69%	58%
Stay in hospital (days).....	42	28
8. Deaths	6	11
Uremia and pyelonephritis.....	4	2
Coronary diseases.....	1	2
Shock and hemorrhage.....	1	6
Cholelithiasis	0	1
Mortality rate.....	6%	11%

Table 1 is a résumé of the work of some thirty urologists, and would seem to show:

1. All of them still prefer some sort of preliminary drainage in prostatectomies, and in 78 per cent of their resections.

2. There is a difference of only five days in favor of resections in preparation.

3. Prostatitis is a factor in only 50 per cent of cases.

4. Untoward results of any degree from an indwelling catheter is present only in 7 per cent of the combined methods. More cases have fever, chills, etc., after than before operation.

5. Almost five times as many complete retentions in prostatectomy would seem to compel more pretentious preparation than in resections.

6. Another reason why resections need less preparation is because many of them are done for symptoms rather than for large amounts of residual urine.

7. The large proportion of damaged kidneys (pyelonephritis) shows that many of them may have their fever, chills, etc., from this reason, regardless of what is done preoperative.

8. Resection deaths outnumber prostatectomies, two to one; but most of them were surgical accidents.

Table 2 is a résumé from a large private hospital, representing the work of general surgeons as well as urologists.

1. Difference in figures here is due to the fact that some general surgeons prefer one-stage operations.

2. A difference of only eight days in favor of resection.

3. Again, the untoward results of an indwelling catheter is present in only 8 per cent of combined methods.

4. Complete retentions in prostatectomy, more than two to one, would seem to necessitate longer preparation.

TABLE 2.—*Private Patients: Comparative Findings*

	Prostatec- tomies, 100	Resections, 100
1. Suprapubic drainage.....	75%	3%
Indwelling catheter, preliminary.....	88%	41%
2. Average days of preparation.....	14	6
3. Prostatitis	60%	49%
4. Fever over 100, chills, etc., preoperative	10%	6%
Fever over 100, chills, etc., post-operative	21%	60%
5. Complete retention	14%	6%
6. Residual urine over 1½ ounces.....	23%	21%
Urine infected on admission.....	87%	67%
7. Kidney damage	51%	37%
Stay in hospital (days), average.....	21	15
Deaths, total.....	2	12
Pyelonephritis and uremia.....	2	8
Hemorrhage and shock.....	0	2
Lung abscess.....	0	1
Opiate reaction.....	0	1

6. Impossible to estimate because most of this having been done before admission.

7. As in charity cases.

8. Resection deaths outnumber prostatectomy deaths, six to one, and 75 per cent of them due to pyelonephritis and uremia. The most important factor in this series bearing on preparation is that 73 per cent of the resections were in one day and operated the next; 75 per cent of the deaths falling in this group. Surely, this shows that preparation might have helped.

In conclusion, I would state:

1. Any group of patients of 65 or over, many of whom have myocardial damage, kidney damage, prostatitis, infected urine, distress, etc., cannot be standardized, but must be an individual problem, both as to operation and type of operation. Certainly, one who has reached the prostatic age is entitled to a rest in bed for a week or more before surgery is done, as a reward, if for nothing else!

2. The title of Doctor Bumpus' paper is really a misnomer, as he does not do what is generally known as a resection, but does a Young punch or, in reality, a near-prostatectomy through a closed bladder, in that he does no deep fulguration.

3. In the ordinary bladder-neck obstruction, time is not an important element, nor are they emergency operations; so why make haste from an economic standpoint?

PULMONARY CAVITY: OPTIMISM SUR- ROUNDING ITS INTELLIGENT TREATMENT*

By F. M. POTTENGER, M.D.
Monrovia

DISCUSSION by Philip H. Pierson, M.D., San Francisco; Sidney J. Shipman, M.D., San Francisco; Edwin S. Bennett, M.D., Olive View.

OUT of much discussion, now and then a truth is established which thereafter seems so self-evident that one wonders why it had not been recognized before. But knowledge is evolutionary. Only rarely is a fact promulgated which is not based on some other well-recognized fact or principle which is closely allied to it and which has been previously applied in daily use.

PRESENT-DAY UNDERSTANDING OF CAVITY FORMATION A RECENT CONCEPTION

Cavities have been suspected in tuberculosis ever since the disease has been carefully studied clinically, and have been proved to exist ever since

* Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

the lungs have been studied postmortem. But the full significance of cavity as a focus from which the disease spreads in the body of the tuberculous patient; the manner in which it infects members of the community at large; and the problem which it presents in therapy is a comparatively recent conception. Formerly, when cavities were found in the lungs the prognosis was considered to be grave. In the minds of most clinicians their presence meant the death of the patient. Today, however, many cavities warrant a favorable prognosis under general hygienic treatment alone, and some of the most serious ones may be successfully treated by our newer methods.

An adequate conception of cavity could not possibly have been had prior to the discovery of the tubercle bacillus fifty-four years ago; and our present conception has been greatly influenced by studies made by means of the x-ray. So the real appreciation of cavity is of very recent origin, and specialists are just now giving out their conception to general medicine.

INFECTION SIGNIFICANCE OF CAVITIES

A fact that all medical men should appreciate and one that I desire to emphasize, is that, from the standpoint of scattering infection, any cavity which throws off bacilli (and nearly all of them do) may not only be dangerous to the life of the one who possesses it, but also to society. I say "may be" advisedly, for it is possible to remove most of the danger by properly directing the patient. Under no circumstances would I create unwarranted phthisiophobia among practitioners of medicine, for when they are imbued with fear intelligent interest lags. One of the great accomplishments of the modern crusade against tuberculosis is the mitigation of the fear of the disease, which formerly possessed the medical profession. To say eradication would be putting it too strongly, for fear still lurks in the background and comes out in the open at unexpected times.

CAVITY RESOLUTION AN INDIVIDUAL PROBLEM

From the standpoint of healing, cavities must be considered individually. Not every patient who has a cavity in the lung is going to suffer from metastases and death, whether or no. It is not a matter of fate. Some will heal readily; others with difficulty; others not at all. The presence of cavity means that the patient must be treated with intelligence in order to afford him the best chance of cure, and those living intimately with him the best chance of escaping infection.

Cavities are not only amenable to treatment, but many of them heal spontaneously. This is especially true of the early cavities found in connection with acute exudative tuberculosis, particularly if situated sufficiently far away from the pleura so that their closure is not interfered with by adhesions; sufficiently far from the hilum to avoid the dense unyielding structures which make up the root of the lung; and sufficiently far from the diaphragm to avoid the pull of its repeated contractions. Other cavities will heal, too, but those just described heal quite readily when properly

treated. This group includes many of those which clinicians have reported on favorably since hygienic living, with rest in the open air, has dominated treatment. Such cavities, if improperly treated, however, pass on to a state in which healing is more difficult or impossible of attainment.

FACTORS IN CAVITY REPAIR

Healing of cavity, whether with or without mechanical aid, depends on establishing, on the part of the patient, an adequate physiologic balance plus an adjustment of lung volume to the size of the thoracic cage. Specific resistance is probably nothing more than a heightening and quickening of normal physiologic action. Early in the course of the disease, when the greater proportion of pulmonary tissue is elastic and free from disease, the chief form of compensation is brought about by emphysema, particularly in the adjacent and near adjacent pulmonary tissues. This, together with the limited motion of the side, which is caused reflexly by the shortening of the apical muscles, particularly the sternocleidomastoideus, scaleni and subclavius above, and the crus and central tendon of the diaphragm below, will prove effective in many cases, provided the patient, through physical and psychical rest, reduces his respiratory and circulatory demands to a minimum.

Some of this type, however, will need further aid in order to bring about closure; and others which appear to be far more serious will yield to simple measures.

TUBERCULOSIS SYNDROMES

Tuberculosis is usually first seen by the family physician or by a specialist who devotes his study to some other phase of medicine whom the patient is led to consult because of the fact that the disease masquerades under symptoms which the patient interprets as belonging to a specialty other than that of the chest; for it must be remembered that tuberculosis often shows syndromes which simulate lesions in other organs and systems of the body so closely that we speak of distinct types. The neurasthenic (rundown condition), cardiovascular, gastro-intestinal, laryngeal, bronchitic, influenzal, pleuritic, and hemorrhagic types are all well recognized.

It is necessary for all physicians to be on the lookout when these syndromes present, and particularly if sputum is present, because this usually means a break in lung tissue with bacilli present; and quite often, if the onset is sudden, it means the presence of cavity. The future of the patient and the interests of the family both demand a diagnosis and the immediate institution of the proper treatment, and the application of the rules which protect other members of the family and society.

With this done, we approach both the healing of the patient and the security of those who come in contact with him with confidence. Not unmindful of the fact that tuberculosis may spread from any focus within the body by way of the lymph and blood stream, yet cavity is the focus which carries with it the greatest danger to the

patient, and is the source which furnishes most of the bacilli which infect others, so it is evident that its early detection is important to both the patient and others.

IMPORTANT RÔLE OF THE GENERAL PHYSICIAN IN CAVITY DIAGNOSIS

Since tuberculosis is usually first seen by physicians other than specialists in tuberculosis, if it is to be diagnosed early it must be diagnosed by them. This is not only their duty, but their privilege. In what way can a physician render a greater service to those patients who seek his advice than by detecting and treating such a serious disease as tuberculosis early, when it is curable, instead of allowing it to progress to a crippling and often a fatal termination? and in what way can he render a greater service to the friends of the patient than by protecting them from becoming infected?

There is nothing in the diagnosis of tuberculosis that lies beyond the capabilities of the well-trained physician, provided he assumes the same interest in it that he does in other diseases and, furthermore, provided he develops a proper diagnostic procedure. There should be nothing to prevent him from diagnosing a cavity when present, except a failure to examine sputum and take an x-ray of the chest; and the necessity of these should both be suggested by the clinical history.

IN CONCLUSION

A systematic method of approach, which consists of three procedures: (1) taking a careful history; (2) examining any sputum that may be present by the concentration method or guinea-pig inoculation, if necessary; and (3) the reading of a good x-ray plate should detect tuberculosis in all but the most difficult cases, and in open cavity cases it should detect all. A tuberculosis-minded profession, and a profession with the confidence in itself which its training warrants, should become the greatest factor in the further reduction of the morbidity and mortality from tuberculosis.

Pottenger Sanatorium.

DISCUSSION

PHILIP H. PIERSON, M. D. (490 Post Street, San Francisco).—I feel that this contribution of Doctor Pottenger's is very timely, for it directs our attention specifically to a phase of the disease which we must consider very seriously.

1. It must be remembered that a very large percentage of pulmonary cavities do not give physical signs, so-called silent cavities; and in view of what Doctor Pottenger has said, it is most important to supplement our examination with good stereoscopic x-ray films.

2. Comparative roentgenograms are essential to determine the disappearance of cavities, and in those cases where conservative measures do not succeed, collapse should be instituted before a cavity has persisted too long. This is particularly important in peripherally located cavities.

3. Cavities must be closed before patients are discharged, for even small ones frequently enlarge and disease is spread from this area very rapidly. I want to emphasize this point particularly, because I feel that most readmissions to hospitals and sanatoria are due to the failure to have the cavity thoroughly closed at the time the patient is discharged.

SIDNEY J. SHIPMAN, M. D. (490 Post Street, San Francisco).—In this succinct discussion of pulmonary cavities Doctor Pottenger has outlined the chief factors in the pathogenesis and healing of tuberculous cavities. It is gratifying to find him stressing the well-rounded concept of tuberculosis, as it affects the individual as a whole and his relation to his environment, rather than taking up the question of cavity formation and repair apart from the resistance and general make-up of the patient himself. Too often nowadays the so-called specialist in tuberculosis, as well as thoracic surgeons, consider the treatment of cavities and forget the treatment of the patient himself.

There are two points of view in approaching the problem of active tuberculosis, particularly as manifested by cavity formation, when, as Doctor Pottenger remarks, the sputum generally contains tubercle bacilli. One is the public health concept which requires isolation of the patient or closure of the cavity to prevent the spread of infection. Undoubtedly, from the long-range standpoint this is the more important attitude, as far as the control of the tuberculosis problem is concerned. This, I suppose, is the viewpoint which leads those who treat tuberculosis to strive so vigorously to close every cavity and render every sputum negative, even when procedures adopted threaten to shorten the life of the individual. The other viewpoint considers the longevity of the patient as of paramount importance, even though he may be a menace to his environment until the time of his death because of the unclosed cavity. In connection with this latter view, it is probably well that Doctor Pottenger emphasized the fact that "it is possible to remove most of the danger by properly directing the patient." Herein lies the educational function of the sanatorium and of the physician. It is probable that the proper attitude for practicing physicians today is a lively interest in the public health problem and a wholesome desire to render sputum bacillus-free, if at all possible, without too much menace to the life of the individual. There are, however, even today, few who advocate extensive rib resections and the like in people of advanced years merely with the hope of closing cavities.

A discussion of the specific factors active in cavity repair is of extreme interest. Some of them we know and some of them we merely suspect, and doubtless there are others which none of us have considered. Certainly, we are hard put to it to explain the behavior of all cavities under various methods of treatment. As Doctor Pottenger remarks, some close with scarcely any treatment at all; others remain open in spite of most vigorous surgical measures. All of us have seen what appeared to be a satisfactory pneumothorax in which thoracoscopy showed no adhesions to be present, and yet a small cavity maintained its size beneath the pleura or in the interior of the lung. It might even cause a bulge at its location, which was difficult to explain except on the basis of one-way valve action in the bronchi, as noted by Chevalier Jackson time and again. Postmortem studies of bronchi leading from pulmonary cavities reveal the high rate of tuberculous infection in the walls and numerous partial stenoses. This factor calls for more complete investigation. With a wealth of pulmonary tissue surrounding a cavity, new explanations must be offered as to why collapse does not occur, and undoubtedly new methods of treatment must be devised to obtain satisfactory healing. One of the interesting features of the study of tuberculosis is the wealth of unexplained phenomena which still exists in dealing with this well-known disease upon which so much work has been done since the discovery of the tubercle bacillus over fifty years ago. Doctor Pottenger has done well to emphasize the part which general medical men should play in examining patients for early diagnosis; but I suspect that so-called "chest specialists" may well join hands with them in searching for the answers to so many questions which still remain enigmas to most of us.

✽

EDWIN S. BENNETT, M. D. (Olive View Sanatorium, Olive View).—I am in entire accord with a feeling of optimism regarding cavity closure in pulmonary tuberculosis, but I should like to emphasize by italics the word "intelligent," as pertaining to the adequate treatment of persons who have pulmonary tuberculosis, regardless as to whether demonstrable cavitation is present in the lungs. Furthermore, intelligent treatment should mean not only

sufficient knowledge on the part of the attending physician, but include his instruction of the patient in order that the patient may become better informed as regards the pathology, care, and after-care of this disease.

Doctor Pottenger quite rightly starts at the beginning in emphasizing that accurate and early diagnosis is essential, and points out as one of his three criteria in making a diagnosis the taking of a careful history. This is strikingly borne out when one realizes that a survey of the records of most large sanatoria will show that, from the history alone, patients when admitted have in all probability had tuberculosis for at least a year and a half. Thus, it is self-evident that history taking is important, and should not be delegated to one who is not a trained investigator.

There is a wide variation in figures as regards the percentage of cavities which close spontaneously, and this is readily understood when one realizes that the size of the cavity and the location in large part determine the outcome in patients who do not receive collapse therapy, as well as those who do. Diagnostic technique has improved in the last decade, until now small intrathoracic cavities may be visualized, which formerly were overlooked. However, it must be admitted that the present technique is not perfect, and that in all probability many cavities which are a menace and harbor great numbers of tubercle bacilli are not now demonstrable by means of any present diagnostic method.

In the intelligent treatment of pulmonary cavitation our efforts are dual, namely, the protection and cure of the patient, and as a public health measure in protecting the contacts. For the sake of the patient and the general public, and for economic reasons, the effort should always be made to close as promptly as possible all cases of open tuberculosis in order that these cases will no longer be a menace to themselves and to others. Thus, the modern and intelligent treatment of tuberculosis is largely a matter of compression therapy. At present no up-to-date sanatorium whose patient population is largely composed of sputum-positive cases is fulfilling its duty to the patient and to the public unless from 70 to 80 per cent of its patient population are receiving some form of compression therapy. Such treatment is not radical, even if begun early, but is simply a proper realization of the problem at hand, namely, making the patient sputum-negative and sputum-free without unnecessary delay. Taken by and large, artificial pneumothorax is unquestionably the greatest aid we have at our command. This procedure alone, or combined with phrenic surgery, will result in cavity closure in a large percentage of cases, with a minimum of risk to the patient. According to the size and the location of the cavity, other procedures (such as temporary phrenic paralysis by crushing, or wax plombage) are often the methods of choice. In recent years, possibly by accident, we have learned that pneumoperitoneum is of therapeutic value, not only for pathology present below the diaphragm, but for unilateral or bilateral pulmonary disease in cases where pneumothorax has not been feasible or possible. In those cases where other simpler methods have failed, a thoracoplasty is indicated, not only for the benefit of the patient, but simply as a public-health measure. However, from time to time patients are seen with a cavity so located that even complete posterior and anterior thoracoplasty will not obliterate the cavity. When such a problem presents itself, at times the only answer is a pneumonectomy with complete extirpation of the involved lung. Radical as this procedure seems now, I feel that within the next five years our knowledge of cases and thoracic surgery technique will improve to the point where this operation will not seem any more radical than did thoracoplasty five years ago.

In all cases of contemplated compression therapy, it is, of course, understood that the patient is entitled to, and must have a careful and complete history, physical examination, and laboratory study, in order to determine as accurately as possible the degree of risk that is involved in any of the procedures heretofore mentioned.

In conclusion, I wish to emphasize that optimism should be the note stressed in the closure of cavitation by intelligent treatment, and we all are indebted to Doctor Pottenger for calling our attention to the fact that we have a perfect right to be optimistic, and that the outlook for the future is becoming brighter all the time.

EXPERT MEDICAL TESTIMONY IN CALIFORNIA COURTS*

By HAROLD DEWEY BARNARD, M.D.

AND

GEORGE E. TUCKER, M.D.

Los Angeles

DISCUSSION by Andrew S. Lobingier, M.D., Los Angeles; Hubert T. Morrow, Esq., Los Angeles; Hartley F. Peart, Esq., San Francisco.

THE frequent contributions to current legal and medical publications on the subject of "expert medical testimony," together with the wide differences of opinion expressed by the contributors, lead the unbiased investigator to conclude that our usual court procedures, as they relate to this matter, have not been and are not now altogether satisfactory.

There may be other methods which might properly be followed if justice is to be obtained in our courts, and both parties to a legal action are to enjoy their guaranteed rights of equality before the law.

One does not need to proceed very far in his investigation of the subject to learn that many representative members of both the legal and medical professions feel that some change should be brought about which will more certainly and equitably serve the ends desired.

WHY COURTS HAVE NOT PLACED EXPERT MEDICAL TESTIMONY ON A SOUNDER BASIS

It is not strange that there should be such widespread differences of opinion among lawyers and doctors as to *what* should be done or the real need for doing anything.

If, under a system of judicial procedure, a staff of attorneys and doctors aligned behind a plaintiff are attacking one goal, while another staff of attorneys and doctors aligned behind a defendant are defending that same goal, in spite of the rulings of the court, it usually follows that the better-trained, stronger team will win the objective.

Trial procedures in our courts, to the uninitiated, too frequently resemble the scenes of a Roman holiday. The interests of justice appear to be overlooked.

Not infrequently counsel and court become so thoroughly enmeshed in the "barbed wire" of legal entanglements that the jury, witnesses, and spectators have difficulty in knowing what it is all about, while Justice, which presumably is to be served by such a procedure, closes her eyes, folds up her scales, lowers her rusty saber, and emerges from the courtroom to await another and more favorable opportunity in which to issue a challenge to the legal rights of members of society.

If such scenes were not so serious and pathetic, and human nature so devoid of humor, they would be looked upon as being nothing other than ludicrous.

* Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

THE DILEMMA OF THE PHYSICIAN IN A PERSONAL INJURY CASE

On those occasions when the doctor, serving as an expert in a personal injury action is drawn into such a picture and called upon to express an unbiased, unprejudiced, truthful opinion regarding the seriousness and extent of a plaintiff's injuries, how in the name of that same justice that is presumed to prevail and govern litigation can an expert be expected to willingly "bite the hand that feeds him"? Once convinced of the merit of a case in which he has been employed, it is only natural that he should, in his desire to be of help and service, become an advocate as well as a witness.

If he is not in the case to help the plaintiff, the court, the jury, and the spectators know that at least he was hired for that purpose. His failure to properly serve the plaintiff's interests is looked upon as evidence of either incompetence or incapability, or, what is more unfortunate, he may even be suspected of "having been reached."

Defendant's experts are in the same relative position with this usual exception—they expect to be paid, whatever the outcome: win, lose, or draw. People who cannot pay are seldom made defendants in such an action. From a financial standpoint, entirely aside from the ethics involved, experts employed on a contingent basis cannot afford to be too neutral, unbiased, unprejudiced, or even truthful: and who would deny the unfortunate plaintiff the right to fight fire with fire and obtain the services of his expert, even though it is understood that his services may not be paid for unless, as a result of a favorable verdict, funds are made available for that purpose? No one would have you believe that medical experts will willingly commit perjury to benefit a client—at least, not often. In their zeal to be of assistance in the winning of a case and to sustain their expressed opinions, they may be forced to withhold information that would weaken their position.

Too many of us have known of instances where experts, when under the fire of belligerent and highly skilled cross-examination, are obliged to parry a thrust that was intended to penetrate the armor with which our present court system forces them to protect themselves as a matter of self-defense.

Too frequently attorneys feel that their well-prepared case is being undermined by adverse testimony, and will resort to methods of attack on a witness that he recognizes as a deliberate effort to impugn his motives and raise a doubt as to his honesty and capability.

THE SITUATION WHEN PHYSICIAN IS PLACED BETWEEN OPPOSING COUNSEL

In a "battle of wits" between opposing counsel and an expert, the attorney is battling over familiar ground—is schooled in the "art of cross-examination" intended to confuse and confound. Forcing his witness to give a "Yes" or "No" answer to a question may be in conformity with ethical

practices in court, while under other circumstances it would be looked upon as a "foul blow aimed below the belt."

Neither lawyers nor doctors can ignore the challenge that such a situation creates.

COURTS NEED AND SHOULD DEMAND UNPREJUDICED EXPERT MEDICAL OPINION

If justice is to be established, our judges should be given the authority, and such authority should be exercised so to conduct the trial of a case that intelligent, capable, unbiased, unprejudiced, non-partisan expert opinion can be placed before him and the jury.

Such opinions should come in response to questions submitted by the court. If they are irrelevant and immaterial, let the attorneys for both parties object, but let the force and effect of these objections result in nothing other than a contribution to delay.

The members of the medical profession have too meekly endured the ridicule that has been directed at them because of their willingness to assist counsel as witness to help him prove his case.

Neither judge nor gentlemen of the jury are capable of determining whether or not the expert is telling "the truth, the whole truth and nothing but the truth, so help me God"; so that if the truth were told they would not be able to recognize it as such.

In fact, opposing counsel too frequently place every legal obstacle at their command in the way of experts to prevent them from telling any of the truth that will seriously damage their case.

PRESENT LEGAL PROCEDURES PREJUDICIAL TO UNBIASED EXPERT MEDICAL OPINION

The court, the jury, the public know that this is true. It is for the purpose of focusing attention on this subject that this paper is being offered.

How refreshing it would be if medical experts were permitted to talk unhampered and unvexed by lawyers' objections, and in an atmosphere of freedom so that the truth would be permitted to emerge.

Is it not reasonable to suggest that the medical expert should be so chosen as to insure intelligent, scientific opinion being brought to bear on the case that is before the court?

Is it too much to ask that the doctor who serves as a medical expert should be looked upon as an honorable member of a dignified profession and entitled to be treated as such?

Are we justified in adding our protest and joining with those other protestants who insist that an expert is entitled to every consideration and demand that he receive it at the hands of both court and counsel?

No claim to originality can properly be made for any suggestions offered here: however, anyone should feel justified in making the observation that perhaps the present system of taking an expert's testimony no longer adequately serves the purpose for which it was established.

EARLY EFFORTS OF CALIFORNIA TO REMEDY COURT PROCEDURES

California was the first state in the Union to pass a law that was intended to overcome some of the objections which were so commonly offered to the usual court procedure. It provides that the court, upon motion of either plaintiff or defendant, may appoint an expert to make the necessary investigations and testify at the trial. It further provides that the court may appoint such an expert on his own initiative.

This law was enacted in 1925 as Section 1871 of the Code of Civil Procedure.

In 1909 Dr. Andrew Stuart Lobingier succeeded in bringing about the adoption of a resolution by the Los Angeles County Medical Association, calling for the appointment of a committee on "expert medical testimony." This committee was to confer with a similar committee of the Los Angeles Bar Association. The two committees, working jointly, were to prepare an act relating to expert testimony to be submitted to the legislature.

It was believed by the members of this joint committee that a bill could be drawn which, if adopted, would lead to the correction of some of the evils that had crept into the usual practice before the courts in connection with the presentation of expert testimony.

It was hoped that their suggested changes would restore the value of the services of the expert, eliminate the disgraceful spectacle of highly conflicting, partisan testimony coming from honored members of the professions, and permit both judge and jury to have unbiased opinions from experts of unquestioned ability. These opinions were to be given full consideration in arriving at a decision.

If time would permit, it would be very interesting to review the history of the efforts of Doctor Lobingier and his associates, which extended over a period of sixteen years. In passing, it should be stated that without the enthusiastic help and support of Mr. Oscar Mueller, representing the Los Angeles Bar Association, Mr. A. H. Koebig, representing the Society of Engineers, Judge Frank Oster, Dr. Thomas J. Orbison, and Senator Jones of San Jose, who gave sympathetic and valuable assistance, this legislation in all probability would not have passed even at the time that it did.

The first draft of a bill was prepared and submitted in 1911. It was rejected by the legislature at that time and a new and similar bill was introduced in 1913, which attracted more attention, but was rejected by the Assembly. In 1915 the bill passed both houses of the legislature, but was vetoed by Governor Johnson. In 1917 and 1919 the measure did not come up for consideration, but in 1921 it passed both houses of the legislature and was vetoed by Governor Stephens. It was finally passed in 1925.

Too much credit cannot be given to Dr. Lobingier, Mr. Oscar Mueller and their associates for the success of this long drawn-out, hard-fought battle, which ultimately resulted in a splendid vic-

tory. Additional credit should be given to these gentlemen because of the many years while they were giving of their time and efforts they also were called upon to finance themselves.

The proponents of Section 1871 felt that under its provisions the major difficulties encountered by the courts in obtaining dependable expert testimony needed for the proper and impartial administration of justice had been overcome.

ADDITIONAL CHANGES NEEDED

While definite improvement is evident, there still remains ample opportunity to go further and bring additional value of expert testimony to the court and forever destroy any grounds that the critic may stand upon when he refers to this form of testimony as a "racket," and those who are employed to offer it as "racketeers."

It not infrequently happens that a plaintiff's attorney, because of the insufficient finances of his client, is obliged to take his case on the basis of a contingent fee. If medical expert testimony is to become available to him, it also must be obtained on a contingent basis.

EXPERT MEDICAL TESTIMONY FOR THE PLAINTIFF

Ethically, perhaps, this is not right, but if there is to be even any semblance of equality before the law the plaintiff who needs help must be in a position to obtain it on any basis that is not illegal. If such expert testimony reveals that it is decidedly partisan, that it is colored and biased and, in the effort to be of assistance, the expert reflects his personal relationship with the injured, he can at least defend his action by the thought that he had a worthy motive. He wanted to help his fellow man who needed it, and if they won their case he was not averse to a little contribution to his pocketbook.

Incidentally, he may feel that to collect his fee his testimony must be convincing—the disability must be established and he must do his part in assisting the jury to determine the measure of damage to be awarded.

EXPERT MEDICAL TESTIMONY FOR THE DEFENSE

A defense medical expert, on the other hand, is in relatively the same position as that of the plaintiff. He also is receiving a fee. He is there to minimize the extent of injury, reduce the amount of award and, if possible, make a permanent disability appear to be only temporary.

Not infrequently, thinly disguised perjury has all of the force and effect of the wholesome truth. At this point, may we ask which of the motivating forces that control human conduct is the more effective, the hope for reward or the fear of punishment?

The expert witness of limited ability may direct his efforts too enthusiastically toward obtaining a satisfactory verdict for the plaintiff because of his hope for financial reward.

The expert witness for a defendant may be guided in his efforts and approach his task with equal enthusiasm, knowing that failure to be impressive and convincing may be a bar to his future employment for a similar purpose.

DIFFICULT POSITIONS OF BOTH SIDES

Such are difficulties of the scrupulously honest expert, who finds his testimony must be injurious to the interest of his employer, that he feels the delicacy of his position. He wishes that he might be permitted to escape. Carefully prepared apologies—though offered in profusion—seldom save his face. Subtle coercion not infrequently puts him on the right track before it is too late. He may even be recalled to correct his mistakes and partially overcome the effect of his damaging admissions.

Insurance companies, because of the frequency with which they are confronted with dishonest efforts to recover damages, are constantly on the defensive, and if they would succeed in preventing excessive awards, or the payment of claims for which there was no liability, their methods must be made to meet the practices which have grown up under our present court system.

Judges of the court, with possibly a rare exception, can be said to be honestly endeavoring to measure up to their responsibilities. There are those who know more, who have a better understanding, who are better informed medically as well as legally, and who conduct a trial more satisfactorily for all parties concerned.

In the light of what is known as to the existence of such conditions as we have enumerated, it is apparent that there is need for the more general use of medical experts on the basis provided for in Section 1871.

QUALIFICATIONS OF A MEDICAL EXPERT

But before leaving this subject, we might for a moment consider *who is an expert?* What qualifications are necessary to segregate a member of the professions from the ranks of those merely licensed to practice and exalt him to the position which places him among those recognized as *experts?* Such a question should not be answered by generalization. It requires that we should be specific and take into consideration all of the circumstances surrounding a given case.

For the purpose of our discussion, however, it may be safe to lay down certain rules which, if followed, would generally lead us to the individual whom we are seeking. We are referring now to the selection of a medical expert.

It must be obvious even to the uninitiated that an expert cannot hope to cover the whole field in which his profession operates. He is not able to qualify as an expert in every part or branch of that field. He who presumes to hold himself out as a specialist on "the skin and its contents" exposes himself to the possible discovery, in spite of his protestations of innocence that he is an impostor.

Present court practices are designed to provide plenty of embarrassment and many unpleasant moments for the expert of this type.

In this respect, members of the medical profession have been guilty of attempting "to take in too much territory," and have unwittingly offered themselves in an unfamiliar environment for the slaughter. Attorneys under such circumstances are willing to accommodate such an individual if they feel that they are adequately prepared. The scene adds color to the play.

He should expect no sympathy if, in the agony of his embarrassment, he wriggles and squirms and looks helplessly to the court for assistance.

The medically unqualified psychiatric expert should not be chagrined if during the ordeal of examination the spectators confuse him with the victim of delusions and hallucinations.

Egotism may be a normal attribute of man, but egomania we know to be a manifestation of a disordered brain.

One who is not an expert, but permits himself to be legally qualified as such, should move cautiously. Our medical associations have established a fairly satisfactory yardstick which can be applied to measure the qualifications of an expert. If a responsible group of fellow practitioners are willing to certify to the courts that a physician is a capable expert in a certain field, the litigants need have no fear that their interests will not be safeguarded, or that the witness lacks the necessary qualifications to meet the demands of justice.

The national movements for certification of experts in the various branches of medicine and surgery should prove to be most helpful to the courts—if the standards are sound and the certificates are issued only to those qualified to receive them.

Conflicting opinions have been so freely expressed by prominent judges and practicing attorneys as to what should be done to correct the existing unsatisfactory use of expert medical testimony in the California courts, that we perhaps should hesitate to offer any suggestions or recommendations.

IN CONCLUSION

In the face of all of these conflicting ideas, the following are our concluding observations:

1. Expert medical testimony in California, except as presented by a court expert, is a purchasable commodity and subject to all the distortion and mental obliquity which such a system makes possible.

2. Section 1871 of the Civil Code is capable of correcting, to an appreciable degree, the altogether too often abused privileges which the partisan expert witness finds open to him.

3. The efficient functioning of Section 1871 is in direct proportion to the finesse of the judges in their selection of honest, impartial and capable medical court witnesses, and in assisting and making possible the proper presentation of their testimony.

4. Section 1871 is worthy of much wider usage in the State of California, and would go a long way to eradicate the ridicule and often contempt which the false position of the medical expert allied with either litigant often brings upon himself and his profession.

5. A more thorough and impartial application of medical science to the needs of law deserves a much greater effort on the part of the two learned professions.

The writers make no professions of profundity in this paper. It is hoped the discussion will provide food for thought.

724 South Spring Street.

DISCUSSION

ANDREW S. LOBINGIER, M. D. (307 West Eighth Street, Los Angeles).—This review of the subject of giving expert medical testimony in the courts of California is a comprehensive detail of the efforts some of us have put forth over a period of many years to establish, through legislation, a dignified and competent method of so presenting such evidence.

The Act (1871), which now is in force, authorizes the court to appoint its own expert when testimony for the plaintiff and defendant is so conflicting as to justify an unprejudiced expert opinion.

The interest in this subject reached an acute stage during the Thaw trial. The Los Angeles Bar Association requested me to discuss the subject of medical expert evidence at a dinner given in honor of the California Supreme Court judges about that time. The history of this development was later published, with a copy of the Act, in the *Journal of the California State Medical Society*.

Mr. Henry Taft, brother of President Taft, of the firm of Cadwallader & Taft, New York, became quite interested in the Act, and wrote me for a copy, as at that time he was moving to have similar legislation passed in the State of New York. California was the first state to pass such legislation, although it was undertaken without good results in many other states in the Union. Recently a bill has been framed to be presented for passage in New York, which is receiving favorable consideration.

It is quite impossible in this brief discussion to consider the many issues which came before us, most of which were discarded as impracticable. Weeks and months of conferences were held before the present form of Act 1871 was adopted. Then it had to be threshed out in the Committee on New Legislation for other protracted periods.

All this tedious and laborious effort is known only to those actively engaged in the long period of sixteen years, wherein these discussions took place. The gentlemen who have so well presented the history of this legislation could not be expected to consider the numberless forms the bill assumed before the succinct and practical text of the Act as passed was adopted.

We believed then and believe now that the Act governing the court's expert would not benefit by any addenda or amendment. We believe it is adequate to meet all requirements in the giving of an unbiased expert opinion whenever the aid of unprejudiced expert evidence is required.

The fact that it has not had a wider and more general employment in the courts in California is in no sense the fault of the Act, or the privilege it confers on the court; the fault lies entirely in the apathy of our judges in exercising their privilege.

Expert testimony has so long been discredited in our American courts, due largely to the incompetency of witnesses called to testify as experts, and to the persistence of the Bar in demanding that the expert they employ shall be favorable to their cause, that even with the Act in force, its practical application is constantly thwarted.

I know of only one way we can improve this lamentable situation, and that is for the medical profession to definitely decline to appear in court to give expert testimony, except as the court's witness. For with this law in force the criticism that expert evidence is worthless and futile, so long charged by judges and lawyers, has quite lost its meaning in California.

✽

HUBERT T. MORROW, ESQ. (837 Van Nuys Building, Los Angeles).—The article by Doctors Barnard and Tucker on "Expert Medical Testimony in California Courts" leaves little to be said that would add any new thought. The writer, having been requested merely to discuss the article, will not assume to repeat any of the views expressed in that article or to bolster it with arguments supporting those advanced by the authors. It is quite patent to anyone with any experience of the subject that practically all of the observations of Doctors Barnard and Tucker are well founded.

The writer recalls the efforts over a period of many years by both the medical and legal professions to provide a statute that would correct the evils mentioned in the above article. Section 1871, Code of Civil Procedure, was the result of those efforts, and it represents the utmost then obtainable. That provision of the law has, in a general way, and to some extent, improved the situation, and in some particular cases it has operated to eliminate the evil of partisan expert medical testimony. However, I believe it is employed in a minority of cases, and even then generally where each side exercises its right under the statute to call its own experts.

The evils pointed out by the article under review could be wholly removed only by denying to any party the right to call his own experts, and by placing in the court's hands the power and duty of appointing qualified and disinterested expert witnesses who would be subject to cross-examination by each party to the litigation. Some such control of expert testimony would be in line with the thought and practice of some foreign jurisdictions, and is not an innovation in juridical thought. Centuries ago in England it was not uncommon for the courts to impanel a jury of matrons to advise the court concerning controverted facts involving pregnancy, and other illustrations might be given of early recognition of the value of independent expert testimony.

While the writer has on numerous occasions observed medical and other experts called by one party or the other, give most conscientious, fair, and honest opinions, such as they would have given if called by the court itself, nevertheless there are far too many instances where experts fall into a partisan attitude that makes them special pleaders for the side calling them. And, of course, in many cases one is confronted by the "professional," venal or incompetent expert witness, whose biased testimony often results in unjust determination of the issues.

The question which the expert is to answer is one upon which the court or jury requires guidance, because it is outside the ordinary experience of laymen. Necessarily the expert gives his opinion upon the subject, either from his own examination (stating the facts in that regard), or from an assumed state of facts recited to him in the form of an hypothetical question which, in turn, is based upon testimony as to facts pertinent to the case. The opinion of the expert should be fair, honest and unbiased, and he should be as far removed as possible from interest in the outcome, personal contact with either party or advocates of such party. Thus only can there be assured reasonable opportunity for fair and correct answer to the technical problem that confronts the court or jury, and which necessitates the calling of experts.

Some twenty-five years ago I had the pleasure of meeting that able man, George Franklin Shields, M. D., and had with him an evening's discussion of the problem in question. Some of the members of the medical profession will recall him. In the course of an address previously delivered by him on the subject of medical expert testimony, he said:

But, gentlemen, expert medical evidence could be made of the greatest value in forwarding justice were it properly introduced. May I suggest two perfectly feasible plans: (1) Let the attorneys of each side select two experts, and

let the four thus chosen agree on a fifth. These five men could, after careful deliberation, bring in a full and useful report on any technical points placed before them. Or (2) leave the matter entirely in the hands of the court, who could call one or a dozen medical men to elucidate, with absolute freedom from bias, any technical points which might arise in a trial. I incline strongly to favor the court having the control, since it would entirely do away with the possibility of partisanship, provided always that the court is what it should be—learned, dignified, and absolutely impersonal. Under this rule the very best men in the ranks of the medical profession would always be ready and glad to give their services, instead of shunning the courts on account of the false position in which they are so frequently placed by the warring attorneys.

In the year 1870 one of the ablest Supreme Court justices of this State, Justice Jackson Temple, said, in deciding a case then before the Supreme Court (40 Cal. at p. 405) :

These witnesses (experts) ought, perhaps, to be selected by the court, and should be impartial as well as learned and skillful. A contrary practice, however, is now probably too well established to allow the more salutary rule to be enforced, but it must be painfully evident to every practitioner that these witnesses are generally but adroit advocates of the theory upon which the party calling them relies, rather than impartial experts, upon whose superior judgment and learning the jury can safely rely. Even men of the highest character and integrity are apt to be prejudiced in favor of the party by whom they are employed.

The above excerpts indicate that the problem in this State has long been recognized by the professions and that there has been little change in the view that expert testimony should be removed from partisanship and elevated to the position where it really can assist in accomplishing justice to all parties.

✽

HARTLEY F. PEART, ESQ. (111 Sutter Street, San Francisco).—The paper entitled "Expert Medical Testimony in California Courts" concerns itself with a subject which is of great importance in the practical administration of justice in the trial courts of this state. While the paper is concerned with expert medical testimony only, the problems presented and the conclusions which are drawn are of great significance to many persons other than medical men. The paper may well be expected to provoke thought and discussion which will ultimately prove of benefit in the better administration of justice in this state.

The authors of the paper quite correctly illustrate the underlying defect in the method now used to introduce expert medical testimony before the trial courts of this state. Too often, under the practice in vogue, an expert witness cannot be considered as unbiased, impartial, and nonpartisan. While it is undoubtedly true that in a great many instances the expert witness is absolutely unbiased, impartial and nonpartisan, the fact remains that many experts who take the witness stand are not so considered by the jury, the judge or the attorneys in the case. The expert is looked upon as an advocate striving to protect the best interests of the person by whom he is paid. The legal justification for allowing a person to give his opinion in any lawsuit is that such a witness is, by virtue of his knowledge and skill, in a position to draw conclusions and state opinions concerning matters about which the jury would have no special information. Thus, an expert witness should be considered as a friend of the court who is willing to use his special skill and knowledge that justice may be obtained. Since an expert witness is in the great majority of cases now considered to be partisan for the reasons pointed out in the paper under discussion, it is understandable why the opposing counsel must use all the learning and skill at his command to discredit the testimony of the witness. As a result, many highly qualified and desirable experts decline to take the witness stand and undergo the physical and mental strain which is involved in defending their opinions.

A question which is of importance to every doctor is whether he may refuse to appear and testify as an expert unless he is paid more than the statutory witness fee. This problem has never been squarely passed upon by the

courts of this state. The problem was presented to the court in the case of

Webb vs. Lewald Coal Co., 214 Cal. 182.

The court decided the case upon other grounds and stated:

The troublesome question as to when it is proper in litigation between private parties to compel an expert witness to give his professional opinion without consent or compensation, though discussed by counsel and by *amici curiae*, does not freely arise on this record. Hence, it will not be here considered.

What little authority there is in this country in regard to this problem seems to favor a ruling that an expert may not be compelled to testify as to matters of opinion without receiving extra compensation therefor.

The broad problems considered by Doctors Bernard and Tucker have been weighed at some length by many writers, both in the State of California and throughout the United States. Hon. Arthur L. Mundo, Judge of the Superior Court, San Diego County, in the May, 1935, issue of the "State Bar Journal," in discussing the problem, takes as his premise the fact that the procedure under which expert testimony is offered in the trial courts is in need of reform. His suggested cure for the evil is to repose the power of appointing experts exclusively in the courts, thus making the expert witness an officer of the court. In order to make this plan feasible, Judge Mundo suggests that a panel of expert medical men and women in each county be submitted to and finally approved by a majority of the judges of the trial court. The county medical societies would certify these experts. When it became necessary for an expert to aid the court, the names of the experts in the field of medicine involved would be placed in a sealed box and drawn in the same manner as jurors are drawn. The litigants would have only the right to disqualify the expert chosen upon properly showing prejudice, bias or interest. In civil suits the cost of securing such expert testimony would be taxed upon the litigants, as the court should determine proper. In criminal cases the charge would be against the county.

Judge Mundo's proposed plan has been criticized by several members of the bar of this state. In general these criticisms are that the best medical experts would not be placed upon the panel, and that such a plan would add to the cost of a lawsuit, thus preventing many plaintiffs from securing justice. (See "State Bar Journal," July, 1935, p. 183.)

The authors of the paper under discussion are among the few writers upon this subject who recognize that California has a statutory law which, if properly carried out, would go a long way toward correcting the abuses of the method now commonly used to introduce expert testimony. Section 1871 of the Code of Civil Procedure provides, in substance, that the judge of a trial court may on his own motion, or on the motion of any party, appoint one or more experts to investigate and testify relative to the matter or matters as to which such expert evidence will be required. It is also provided in this section that the litigants may produce their own expert witnesses, and it is further provided that the judge may limit the number of experts to be called by any party. It is quite clear that this law is an attempt to take a middle ground. While it has not proved as efficacious as it might, it seems to this writer that with coöperation on the part of the county medical societies, along the lines suggested by Judge Mundo, with the judges of each Superior Court, the evils of our present system, in so far as expert medical evidence is concerned, would in a large degree disappear. Since this proposal involves no change in statutory law or in the theory of the proper function of an expert witness, it would seem that the proposal should be entitled to a trial.

The conclusions reached by Doctors Barnard and Tucker show that much careful thought and consideration have been given to this very troublesome problem. As this problem is essentially practical and not merely academic, the paper under discussion is entitled to the serious consideration and discussion of the members of the medical and legal professions. It is only in this manner that we may obtain a necessary reform in the administration of justice.

THE THYMUS IN HEALTH AND DISEASE*

By PAUL MICHAEL, M.D.
Oakland

DISCUSSION by Francis Scott Smyth, M.D., San Francisco; Howard L. Eder, M.D., Santa Barbara.

INCREASED attention to endocrin disorders in the last few years has stimulated our interest in the thymus. Experimental work on fish and mammals has, as yet, failed to establish the full significance of this gland's function. The scope of this paper includes an embryologic and physiologic discussion, with a report on the study of two hundred clinical case histories and their protocols.

EMBRYOLOGY

Although we know it originates from the ventral aspects of the third and fourth branchial clefts, the thymus anlage descends from the pharynx to lie in the lower neck and in the thorax over the base of the heart. Its origin establishes it as an epithelial organ, but the microscopic make-up is unmistakably lymphoid. Because of the embryologic association of the thymus and parathyroid glands, there is a certain structural and functional relationship: structural, in that parathyroid tissue may be found within the thymus; and functional in that both are associated in some way with calcium metabolism. The thymus is divided into two main parts—the neck thymus and the thoracic thymus. It has two lobes and is composed of cortex and medulla, all enveloped within a fibrous capsule. The adenoid tissue of the peripheral cortex is more closely packed than that in the medulla. The lobes are subdivided into lobules held together by an interlobular connective tissue. The smaller lobules, 5 to 10 millimeters in diameter, are further divided by septa into smaller compartments, each of which contains several secondary lobules. The secondary lobules are made up of many primary and secondary follicles resembling lymph follicles in structure.

Scattered through the gland are Hassall's corpuscles—large, round or ovoid bodies, which stain faintly and have irregularly concentric laminations. These bodies may have some endocrin importance, or may be products of degeneration; their origin and function, for the present, however, must still be left to conjecture. The blood vessels run in the interlobular connective tissue and give off branches which penetrate the follicles as a large capillary network. Accompanying this network is a very luxuriant lymphatic vascular tree.

FUNCTION

Research work on the function of the thymus gland is principally confined to animal experimentation. The history of the thymus problem is a laborious one, and will be summarized in brief.

Restelli,¹ in 1845, showed that the thymus was in some way connected with the rate of growth during early development. Friedleben,² in 1858,

likewise showed the significance of the gland in osseous development and believed it also to be of hematopoietic importance. Basch,³ in 1902, demonstrated again that the gland was concerned with growth and also the calcification of bone. Soli,⁴ in 1910, showed that thymectomy in chickens resulted in the laying of eggs without shells. Hewer,⁵ in 1914, continued the studies started by Basch and demonstrated the relationship of the thymus gland and calcium metabolism. Klose and Vogt,⁶ in 1914, removed the thymus in young animals and claimed this resulted in adiposity and cachexia, accompanied by spontaneous fractures. The painstaking work of Park and McClure,⁷ in 1919, set forth in their monograph on the thymus gland, threw the entire subject into turmoil by questioning most of the experimental work done up to that time. They felt that the thymus had little influence on the growth of the body or alteration of the hair and teeth. They admitted that there may be some slight retardation in development because of delayed calcification. The period 1919 to 1931 was the golden era of romance for the thymus gland. Numerous obscure conditions were credited to the thymus, and all unusual deaths were accounted for on this basis. Young and Turnbull,⁸ in 1931, attempted to refute this entire theory, and claimed that the thymus was in no way associated with sudden death. Although unable to explain the method, most American observers believe that status thymicolymphaticus is a condition *sui generis*, and not infrequently associated with otherwise unexplained fatalities.

Some of the most significant animal experimentation work has recently come from the Philadelphia Institute for Medical Research. Rowntree⁹ and associates, using an acid aqueous extract of the neck thymus of young calves called karkinolysin (Hanson,¹⁰ 0.6 gram of raw thymus per cubic centimeter), experimented on white rats obtained from the Wistar Institute. These rats were injected intraperitoneally daily for six months. In the first generation the animals were heavier, bred more frequently, and had larger litters of heavier rats. No definite changes occurred in the second generation in the first six litters, but in the seventh to the eleventh litters evidence of precocity occurred. In the third to the seventh generation, acceleration in the rate of growth and precocity were marked, and increased with each succeeding generation. Rowntree⁹ reported certain chemical changes which occurred in these animals. Thymus-treated rats, from the second to the fourth generation, showed an increase in serum calcium, ranging from 11.4 to 13.3 milligrams per cent, with an average of 12.3; and the inorganic phosphorus ranging from 4 to 7.5 milligrams per cent with an average of 6.1. The controls showed a serum calcium from 9 to 11 and the phosphorus from 3 to 4 milligrams per cent. There was no deviation in the blood count. X-ray studies showed increase in the size of the bones, with earlier appearance and calcification of the ossification centers. Thymus extract in small doses showed no reaction on the heart, but large amounts resulted in shock, fall

Chart 1.—Comparative weights of thymus

in blood pressure, and auriculoventricular heart-block. All these results were obtained by using the old thymus extract prepared by Hanson in 1930. Fresh extracts showed very little stimulation, and oral administration was ineffective.

CLINICAL APPLICATION

The clinical conception of this problem is even more confused than the experimental. The unfortunate weakness is that most experimental findings are not borne out in their clinical application. It is natural, then, that much incorrect pathologic significance has been given to the thymus gland, partly because we have failed to establish the normal. It appears that the thymus is enlarged in Graves's disease, Addison's disease, acromegaly, status lymphaticus, sometimes in rickets, asthma,¹¹ and most often in myasthenia gravis. The thymus may be enlarged in eunuchs, and its involution is delayed in early castrates. It normally involutes after puberty, probably inversely as the development of the reproductive organs takes place. It was thought by the older writers to diminish in size in starvation, inanition, and general wasting diseases, and to enlarge in certain acute diseases in children or young adults.

MATERIAL FOR THIS STUDY

It was upon these last questionable tenets that work was originally instituted as to qualitative and quantitative changes in the thymus gland, and the development of a normal weight curve. The glands were completely removed, weighed, studied grossly and microscopically, and correlated with the clinical findings. Six cases of lymphoblastoma and eight cases of apparent status thymicolymphaticus were eliminated from the study, some of these latter having been reported in a previous communication.¹² The study includes two hundred cases, of which one hundred were children

under fifteen years. Friedleben,² Kasarinow,¹³ Von Sury,¹⁴ Hammar,¹⁵ Ronconi,¹⁶ Klose,¹⁷ Bratton,¹⁸ Scammon,¹⁹ and Boyd,²⁰ all agree as to the average birth weight—9 to 14 grams. The majority of the investigators reported much higher puberty rise and prepuberty rise than my series, while Young and Turnbull⁸ and Hammar¹⁵ reported weights in adults far in excess of those seen in the present series.

Time does not permit a complete correlation of the clinical and autopsy protocols established in these two hundred cases. A summary of the findings, however, includes the following points: The average birth weight was 12 grams. There was then a steady decline to the age of five years, when the average weight was 10 grams. From then on to puberty the decline was more gradual, with the average weight being at this time 9 grams, establishing almost a continuous horizontal line. From puberty on to adult life, however, there was another drop. The average weight in adults was 2.5 grams. The thymus in males, on the average, was slightly heavier than that in females, although the difference was not always appreciable. There was no correlation between acute infectious diseases and enlarged thymus. It appeared that the enlarged thymus in certain diseases, such as diphtheria, fulminating septicemia, etc., was part of an inherent constitutional state of the individual, contributing to the disease rather than the result of it, indicating a low resistance or lack of immunity. Evidence favored the fact that an enlarged thymus gland was probably a primary enlargement rather than a secondary one, resulting from toxemia. As acute, subacute, and prolonged wasting diseases were included in this study, no definite correlation was seen between the latter conditions and atrophic thymus. As a matter of fact, this group conformed to the normal established by the series. There is no satisfactory explanation forthcoming accounting for the discrepancy between my figures and those reported in other series. Complete extirpation was done and accurate weighing was maintained throughout.

No study of the thymus gland is complete without at least mentioning the condition called lymphatism, or status thymicolymphaticus. Probably one of the most controversial, certainly one of the least understood, it remains one of the most frequently mentioned conditions. Lymphatism is a state in childhood, or occasionally in adults, when lymphoid tissue, normally present in but small amounts, is found to be flourishing and luxuriant. Not only is the thymus itself larger than normal, but the lymphatic tissue generally is hyperplastic—especially in the lymphoid follicles in the mesentery and along the gastro-intestinal tract. The body may be characteristically thin and undeveloped, or may show an unhealthy, pale, flabby overgrowth. There is usually a small heart, small blood vessels, frequently with defective walls, and hypoplasia of the adrenals. There may be a marked allergic tendency¹¹ or some exudative diathesis. Unexplained death even from trivial causes may occur, and attempts at explanation may bring to

mind the possibility of an exudative diathesis, an overwhelming toxemia from excessive lymphoid breakdown²¹ or fatal heart-block from excessive calcemia.⁹

SUMMARY AND CONCLUSIONS

1. The thymus gland is reviewed embryologically, physiologically, experimentally, and clinically.

2. A brief review of the literature is included.

3. Two hundred case histories are summarized in which the thymus was studied. Birth weights agreed with those reported by other observers, but puberty weights and adult weights were much less than those generally given. There was no definite relationship existing between enlargement of the thymus and infection, or atrophy of the thymus and wasting diseases.

4. A résumé of status thymicolymphaticus is given, and the claim that it is a condition *sui generis* sustained.

434 Thirtieth Street.

DISCUSSION

FRANCIS SCOTT SMYTH, M. D. (University of California Hospital, San Francisco).—The subject of Dr. Michael's paper is one which will precipitate considerable argument in any medical group. The older orthodox viewpoint, that the thymus enlargement is in itself responsible for certain sudden deaths, has been in some instances a smoke screen to hide our ignorance. In the first place, post-mortem examinations of sudden deaths in healthy children before puberty should show normal healthy tissues in contrast with those examinations after wasting illnesses. While Doctor Michael's study shows that thymus hypertrophy is still independent of such conditions, the studies of Boyd would tend to show a distinct difference in the thymus of a healthy child and that of a sick one.

A number of years ago Dr. O. M. Schloss had his house staff correlate x-ray diagnosis and pathologic measurements of the thymus. While our series was small, we were convinced that there was frequently a false interpretation of x-rays, as judged by the actual size of the thymus.

More recently Waldbott and others have collected evidence which strongly suggests that anaphylactic-like episodes may be concerned with some of the instances reported as thymic deaths.

It is well, then, not to overlook other causes, such as cocain shock, anaphylaxis, etc. On the other hand, despite the discrepancy between the x-ray and the postmortem findings, it is probably safer to resort to x-ray therapy, when careful x-ray suggests thymic enlargement, than to philosophize on the inadequacies of medical methods.

Unquestionably, from studies such as Rowntree is making, we will find the nature and place of the thymic hormone in the present maze of endocrines. Mention should be made of the clinical observation of symptoms similar to thyrotoxicosis apparently associated with thymic hyperplasia and responding to thymic extirpation. Mention should also be made of the frequency with which aberrant parathyroid tissue may be found in the thymus gland.

✽

HOWARD L. EDER, M. D. (1421 State Street, Santa Barbara).—Doctor Michael has given us a very complete, interesting and illuminating article on the thymus gland. Many articles relating to this rather small gland published during the past twenty years have caused considerable confusion in the minds of not only the doctors, but also the lay public. Recent articles have helped to straighten out some of the confusion in the minds of the doctors. No doubt, in the near future we will know enough about this small gland and other ductless glands to aid us materially in the diagnosis and treatment of certain diseases.

I am sure that in pediatrics a syndrome complex is encountered which, whether it is caused by the thymus gland or not, at least responds to x-ray therapy over that region. These cases present a rather typical picture, consisting usually of vomiting, sinking spells with cyanosis, colic, and irritability. These babies cause great concern to the mothers, and when undiagnosed do very poorly. During an attack the simplest procedure is to hold the baby head-down until the cyanosis disappears.

The x-ray picture generally shows an enlargement of the thymus gland, not only in breadth but also in unusual thickness. Auscultation in this region will usually give diminished heart sounds and there is a dullness on percussion. X-ray therapy has always relieved the symptoms of this peculiar condition in the cases I have observed.

The lay public is very much concerned about the enlargement of the thymus. Parents frequently ask to have a new-born baby x-rayed for possible enlargement of the thymus. They also ask frequently to have the thymus x-rayed before an anesthetic, particularly for the removal of tonsils.

So many articles have been published on status thymicolymphaticus in the past that it is impossible to convince patients that this condition is probably coincidental with sudden deaths. It will take a long time to convince the public that the thymus is of great importance in growth and development, but probably plays little part in disease.

MISSED ABORTION *

By J. MORRIS SLEMONS, M.D.
Los Angeles

DISCUSSION by C. Frederic Fluhmann, M. D., San Francisco; Frank W. Lynch, M. D., San Francisco; Norman H. Williams, M. D., Los Angeles.

THE belief has become traditional that a vigorous reaction on the part of the uterus will promptly expel the product of conception whenever the fetus dies. As a rule, it happens so; and yet an interval of six weeks often passes before the abortion occurs. Should the delay be longer—several months, rarely a year or more—many vexing questions will arise; some theoretical, others quite practical in their implications. At times the interwoven medical and social features assume a legal aspect, and may provoke a lawsuit. The best known illustration of this contingency relates to a distinguished British gynecologist, a generation ago, who failed to consider all the possibilities in the case of a prominent London woman whose husband had been absent in India a year when she aborted a disintegrating ovum which presented an early stage of development. That the husband could not be responsible for the pregnancy was the opinion the gynecologist expressed; and in the courts he lost a suit brought against him for defamation of character. In fact, the prolonged retention of a dead embryo created this embarrassing domestic situation. Missed abortion was the correct diagnosis.

FREQUENCY

Missed abortion of impressive duration was once thought to be an extraordinary complication. Now, we know, it occurs much more often than intimated by the report of E. Fraenkel,¹ in 1903, who was able to collect only 105 cases, including his own. Current textbooks reflecting the personal experience of their authors agree that its incidence has been underestimated. Thus, Taussig,² in a comprehensive monograph just published, says that one-tenth of all the abortions in his own practice were retained a sufficient length of time to permit classification as "the missed" variety.

This complication is treated somewhat more frequently in private practice than in institutions which serve the poor. Malnutrition, fatigue, jolts and jars, hard work of all kinds, favor abortion whether the fetus is alive or dead. Among the well-to-do, on the other hand, when premonitory symptoms develop, treatment becomes insistent and often succeeds in abating a stimulus that otherwise would set in motion the expulsive muscular mechanism. The elimination of exercise, enforced rest to the point of keeping a patient in bed, and the abundant administration of sedatives, all assist toward defeating nature in her purpose to rid the woman of a fruitless pregnancy. And so, paradoxically, modern precautionary measures which safeguard the prospective mother increase the incidence of missed abortion.

REPORT OF CASES

CASE 1.—Age, 23. Gravida 1. Last menstrual period began September 13, 1930. Normal progress for four months; never felt fetal movements. January 5, 1931, fundus nine centimeters above symphysis. January 14, abdominal pain of moderate intensity, one day; no bleeding. January 21, uterus the same size as one month ago. February 18, uterus smaller than at last visit and cannot be felt abdominally; on vaginal examination, found a retroverted uterus about the size characteristic at third month of pregnancy. General health excellent. When told of possibility of missed abortion, the patient insisted nothing was wrong.

Operation.—February 27. Dilatation of cervix and removal of ovum with placental forceps; curettement.

Pathologic Report.—Fragments of placenta. Fetus nine centimeters long; tissues dry and tough (mummification). Microscopic study shows shrunken chorionic villi. Endometrium regenerating: stroma cells small, glands resemble those of nonpregnant uterus rather than of decidua. Estimated retention period of dead fetus was three months.

1 1 1

CASE 2.—Age, 43. Gravida 10. Eight living children; miscarriage at three months in 1922. L. M. P., January 5, 1927. Mild attack of influenza in February. X-ray treatments for pruritus vulvae during March and April. Slight vaginal bleeding for two days early in May and again on May 26; no cramps or backache. On June 11 she arrived in Los Angeles after a transcontinental railway journey, and shortly after reaching the hotel she noticed vaginal bleeding. The husband, a physician, thought pregnancy out of the question. The uterus, asymmetrically enlarged, corresponded in size with the third month of gestation. A round mass within the uterus at the right cornu, four centimeters in diameter, was interpreted as a myoma.

Operation.—June 14. Dilatation of cervix; digital exploration of uterine cavity. The mass just mentioned proved to be an hematoma mole. Contents of the uterus removed with placenta forceps; cavity packed with gauze. Bleeding scant until pack was removed after being in place twenty-four hours. Subsequently, excessive lochia for ten days, when uterine cavity was explored and no placental fragments found. At husband's request, radiation was employed and bleeding ceased. Recovery.

Pathologic Report.—Placenta penetrated by and covered with old blood-clots (Breus mole). In the center of the mass was a macerated embryo 3.5 centimeters long. Estimated retention period was four months.

1 1 1

CASE 3.—Age, 35. Gravida 2. One living child delivered by low forceps on account of maternal toxemia (albuminuria). L. M. P., February 16, 1931. No ailments in early months. June 12, fundus eight centimeters above symphysis. July 13, no quickening; uterus the same size as a month ago; slight cramps and "spotting." On August 13 the hormonal urine test (Friedman) was negative.

Operation.—August 15. Dilatation of cervix and removal of uterine contents with placental forceps.

Pathologic Report.—Fetal sac intact, containing macerated embryo nine centimeters long. Estimated retention period was three months.

1 1 1

CASE 4.—Age, 32. Gravida 3.—Two illegal abortions. L. M. P., May 15, 1930. When first seen, July 20, the uterus was enlarged and soft, but could not be outlined clearly on account of chronic inflammatory adnexal disease. The hormonal urine test (Friedman) was negative. July 31, severe abdominal cramps and moderate uterine bleeding.

Operation.—July 31. Dilatation of cervix; removal of uterine contents with placental forceps.

Pathologic Report.—Fetal sac intact, containing an amorphous lenticular mass, the embryo, one centimeter long, five millimeters thick. Estimated retention period was six weeks.

* Read before the Obstetrics and Gynecology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

CASE 5.—Age, 23. Gravida 1. L. M. P., July 15, 1932. Her physician, consulted September 28, made a diagnosis of pregnancy. Quickening was never felt. No ailments. On February 3, 1933, as the abdomen failed to enlarge, the physician doubted the correctness of his primary diagnosis and was confused, especially by a negative hormonal urine test (Aschheim-Zondek). Then I saw the patient in consultation, and found the uterus approximately twice normal size; otherwise nothing noteworthy. Suspecting a missed abortion, dilatation and curettement were recommended. This was done by her physician, who reported the removal of placental tissue. Estimated retention period was six months.

CLASSIFICATION

How long must the dead fetus be retained before the diagnosis of missed abortion is warranted? Heretofore, attempts at definition, somewhat arbitrarily, were based upon a comparison of the developmental age of the embryo with the menstrual age of the pregnancy. Guided in that way, clinicians regarded a retention period of six weeks as requisite to correct classification. All the cases of this series fulfill that requirement: an interval of from six weeks to six months elapsed between the death of the fetus and the termination of pregnancy by instrumental means.

In the past no reasonable objection could be raised against the "time criterion"; but now, having at hand the hormonal urine test, it seems preferable to differentiate cases on that basis. In other words, the diagnosis of missed abortion, in my judgment, should be made only after the Aschheim-Zondek or Friedman reaction has become negative. Of course, it does not become so immediately after the fetus dies. As long as vitalized placental tissue remains, the test will be positive; until it becomes negative we must consider the possibility that the uterus will empty itself spontaneously. This suggestion, however, applies merely to the first half of pregnancy, the period corresponding with the accepted use of the term "abortion"; nearer term, Wilson and Corner³ find that a positive hormonal urine reaction persists far too long after fetal death to serve the practical purposes of diagnosis and treatment.

The hormonal urine test was negative in three of my cases. Although not employed in the other two, they were correctly classified; the uterus of one of them contained a hematoma mole, the other a mummified fetus.

CLINICAL MANIFESTATIONS

In contrast with the frank, troublesome manifestations of most bodily derangements, the maternal symptoms of fetal death are conspicuous for their negative character. Breast engorgement vanishes, nausea and vomiting cease. A good appetite replaces a distaste for food. The tendency to lose weight is arrested; often the patient begins to gain, gradually and moderately. Relieved of the distinctive ailments of the early months, the prospective mother assumes everything is going as it should.

Invalidism in these cases, which impressed Litzenberg,⁴ must be extraordinary. None of my patients complained of a foul taste, an offensive leukorrhea, chilly feelings, or malaise; neither were they profoundly anemic, feverish in the

afternoon, or mentally disturbed. That infection seldom occurs is a remarkable fact, probably explained by organic readjustment to the changed embryologic situation. The muscular wall of the uterus becomes firmly retracted, its blood vessels undergo alterations which narrow the lumen and the endometrium begins to regenerate. None the less, precaution must be unremitting against the introduction of contaminating material; vaginal examinations, limited in number, will be made with strict aseptic technique and the marital relation forbidden.

A pregnant uterus of stationary or diminishing size provides the most significant clinical evidence of fetal death. At first the patient fails to notice that her abdomen is not growing larger; and, if she has not yet reached the time for quickening, this sign, or its absence, cannot be utilized. On clinical grounds the physician forms an opinion, beyond cavil, only after reexamination of the patient at the end of a month. Meanwhile, if the laboratory reports a negative hormonal urine reaction, the debate is closed.

As a rule, very slight symptoms of threatened abortion follow directly upon fetal death, symptoms often insignificant to a patient accustomed to much more severe cramps with menstruation and indifferent to a faint discharge of blood. Should she communicate with her physician, he will recommend sedatives and continuous rest in bed. Typically these measures soon afford relief, and she resumes her customary routine for a longer or shorter interval until outspoken signs of abortion appear, or clear proof of fetal death warrants surgical treatment.

Neglected cases, women who first seek medical advice long after the fetus has perished, formerly presented great diagnostic difficulties. It was not easy to decide whether or not the uterus contained a pregnancy; and, if so, was the embryo alive? In these circumstances modern methods become most helpful, especially the hormonal urine test. A positive result impels delay; a negative one at least permits active treatment without the hazard of ending a pregnancy unwittingly. Even today, however, the differentiation of missed abortion and myoma can be perplexing, as I once had occasion to learn. Upon arrival from the East the patient began to bleed shortly after reaching a hotel and was brought to the hospital by her husband, a physician, who thought pregnancy out of the question. The history and the pelvic examination were in harmony with the diagnosis of myoma, but at operation a hematoma mole was found.

Clinical study seldom, if ever, discloses the cause for retention of the fetus. Consequently, in the case just mentioned it is noteworthy that repeated radiation had been used for the treatment of pruritus vulvae. In another case pelvic inflammatory disease had persisted since a former pregnancy was aborted illegally. There the chronic pathologic lesions, which included metritis, are suspected as responsible for uterine inertia. Isolated cases, to be sure, even correctly interpreted,

fail to indicate the broad principles which underlie prolonged retention of the fetus. For these we must look further.

PATHOLOGY

Anatomic research has taught a great deal with respect to the structural changes which precede and accompany the immature arrest of embryologic development. With a rich material, contributed by midwives as well as physicians, Mall⁵ demonstrated in abortions that the primary defect of the gestational organization centers around the nutrition of the embryo, and that it dies before the placenta loses its vitality. Primarily, the maternal tissues are often at fault, but not always; the protoplasm of the embryo may be defective. Less intense grades of malnutrition, not severe enough to cause death, interfere with perfect embryonic development. These focal imperfections, in particular intra-uterine amputations, have been studied by Streeter.⁶

When the embryo dies, it becomes a foreign body—a permissible description for want of more exact information—and nature endeavors to cast it off. To this rule there are a few exceptions. A. W. Meyer⁷ found that resorption of a conceptus occurs in women just as in multiparous mammals. He learned, too, that the embryo vanishes before the structures which protect it. This eventuality, of course, will be impossible unless development has ceased at an extremely early stage. Later the bulk and composition of the ovum prevent complete dissolution and absorption; it must then be removed by way of the birth canal. Presumably the uterus always tries to accomplish that result and occasionally fails because its contractions are either too infrequent or too weak.

Seeking the underlying cause of uterine inertia, it is not difficult to choose the path to follow. Let us see what help has already been had from endocrinal research. Of this there have been two pertinent varieties: one relates to the corpus luteum hormone, progesterone; the other to estrin, a hormone of great importance in fitting the uterus for parturition.

HORMONAL CONTROL

Snyder⁸ demonstrated in the case of rabbits that the intravenous injection of urine from a pregnant woman postponed the birth of their young, and he attributed their retention in the uterus to the action of hormones. His conclusions were based upon a brilliantly conducted research the steps of which may be very briefly recapitulated. A small amount of chorionic gonadotrophic (anterior-pituitary-like) hormone thrown into the maternal circulation induced spurious ovulation, although the rabbits were already pregnant. The ovarian follicles which responded to this stimulus underwent the customary transformation into corpora lutea. Accordingly, parturition did not occur upon the ordinary date (thirty-two days postcoitus), but was deferred until the induced corpora completed their life cycle, postponing the delivery until the fortieth day, and prolonging pregnancy by a period 25 per cent of its usual duration. Specifically, the delay was due to the

artificial production of corpora lutea and the consequent influence of their hormone. Snyder argues convincingly that the rabbit's uterine musculature remains quiescent during pregnancy in response to progesterone. Does the same reasoning apply to women? Probably so. At least this inference has the support of collateral evidence from other sources.

In 1903, L. Fraenkel⁹ observed that women aborted when the corpus luteum was ablated in early pregnancy, or the ovary containing it removed. In other words, as it now appears, the depletion of progesterone permits the establishment of efficient uterine contractions. More recently, Corner and Allen¹⁰ have shown that the corpus luteum functions in this way, among others. Clinical application of their work, reported by Falls, Lackner, and Krohn,¹¹ emphasizes the inhibitory effect of progesterone upon cases of habitual and threatened abortion.

It is significant, as Streeter remarks, that the expulsion of a conceptus is retarded conspicuously when fetal death occurs between the sixth and the seventeenth week of development. At this period the corpus luteum is relatively large; the placenta small; the amniotic fluid less abundant than later. Each of these environmental factors must be taken into account before the explanation for missed abortion becomes full and final: the corpus luteum because it produces progesterone, the fetal sac because its estrin content continues to be comparatively poor, while the bulk of the pregnancy remains small.

Estrin (also called female-sex hormone, theelin, progynon, folliculin, and by still other names) occurs not only in the fluid of the ovarian follicle, but also in the placenta, fetal membranes, and amniotic fluid. Unquestionably, it participates in the preparation of the uterus for the act of labor; but its sphere of influence has not been definitely ascertained. Some writers believe it sensitizes the muscle and nerve elements of this organ. Furthermore, Robinson and his coworkers¹² assume hypothetically that estrin stimulates the posterior lobe of the pituitary to elaborate the characteristic hormone, distinguished for its ecobolic properties.

If the pregnancy is normal the administration of estrin to women never causes abortion, according to Robinson, Datnow, and Jeffcoate; on the other hand these authors found the same treatment effective whenever a dead fetus was retained. Among twelve cases of missed abortion given massive doses of estrin, only two failed persistently to react, three responded following additional medication, the remaining seven expelled the contents of the uterus spontaneously, "after an interval up to seven or eight days." Parenthetically, estrin had no effect upon several patients with incomplete abortion and one with hydatid mole.

Such results will inspire further trial of this therapeutic agent, especially since Spielman, Goldberger, and Frank¹³ reported several years ago that estrin disappears from the mother's blood after death of the fetus. During normal pregnancy its presence in the blood has long been recog-

nized, and its abundance in the urine was recently reaffirmed by Cohen, Marrian, and Watson,¹⁴ who add: "the hormone first presents itself in an adynamic form, as estrone and estriol, in combination with glucuronic acid." At the approach of labor the bond is broken, liberating a potent form of estrin. Ultimately the functions of this endocrine secretion will be defined more clearly. At present it appears that during normal pregnancy two hormones, progesterone and estrin, hostile to each other in some respects, are equilibrated; preliminary to labor the latter gains the upper hand. Conversely, the inertia responsible for the prolonged retention of a dead fetus is probably associated with a deficiency of estrin and a surplus of progesterone.

TREATMENT

Radical treatment of missed abortion, either medical or surgical, must inevitably await proof of the death of the fetus. Subsequent delay will be governed largely by the patient's attitude, a permissible concession, for procrastination rarely leads to complications. Nevertheless, with the diagnosis established, the physician should recommend active treatment since the removal of the derelict pregnancy alone will restore the normal functions of the reproductive organs.

In due time the therapeutic merits of estrin will be fully ascertained. At present commercial preparations of the hormone are expensive and the correct dosage has not been announced. On theoretical grounds it was predicted that pituitrin would act weakly during the early months of pregnancy because of the antagonism of progesterone. So it does. Induction by means of bougies contributes infection too often and, besides, it frequently provokes bleeding. Therefore, when therapeutic abortion has been agreed upon, the logical choice of treatment today is surgical. If the attending physician in all conscience feels the need of assistance, there will be ample time to make such arrangements as best assure a satisfactory end-result.

In general the operation consists of dilating the cervix, loosening with a finger the retained material and removing it by the use of blunt forceps. A sharp instrument, a curette, may perforate the uterus. At times vaginal hysterotomy becomes the preferable operation. Irrespective of the type of procedure selected, preliminary preparations for packing the uterus are imperative to obviate postpartum hemorrhage.

As a rule the convalescence will be smooth, but in one case of this series, that of hematoma mole, excessive bleeding continued for days after removal of the pack. It ceased following radiation, employed at the request of the husband, a physician; sterility ensued. Likewise, the woman with chronic pelvic inflammatory disease has not become pregnant again. The remaining three patients have borne children subsequent to their experience of missed abortion. Finally, it should be noted that a few, very few, cases of repeated missed abortion have been recorded in medical literature.

SUMMARY

No longer a rare complication, missed abortion has had relatively slight comment in medical literature because until recently very little was known about the cause of the underlying uterine inertia when a dead fetus is retained. Negative clinical manifestations and relief from the common ailments of the early months of pregnancy mislead patients to believe that all is going well. Sound diagnosis will supplement the observation of arrested uterine growth with proof that the hormonal urine reaction has ceased to be positive. Anatomical studies reveal that the fetus dies before the placenta loses its vitality. Endocrinal research indicates a deficiency of estrin, a surplus of progesterone; a situation harmonious with persistent uterine inertia. In general treatment remains surgical, since drugs are almost always inert and hormonal therapy has not as yet been accurately defined. At operation two hazards must be kept in mind, perforation of the uterus and profuse hemorrhage.

DISCUSSION

C. FREDERIC FLUHMAN, M.D. (Stanford University Hospitals, San Francisco).—The condition of "missed abortion" is not only of considerable importance from a clinical standpoint, but it presents certain problems which are inevitably associated with the cause of the onset of

labor. As Doctor Slemmons points out, modern investigators have sought to explain this phenomenon on an endocrinologic basis, and three main factors have been considered: (1) progesterin, a specific product of the corpus luteum, which inhibits uterine motility; (2) estrin, which sensitizes the smooth muscle of the uterus so that it responds more readily to the oxytocic action of (3) the posterior pituitary principle. On the basis of animal experimentation, it has been possible to expound a number of theories; but it must be remembered that the problem in the human is complicated by the appearance of a new hormone which is not found in nonpregnant individuals nor under any conditions in ordinary laboratory animals. This substance, the "chorionic gonadotropic hormone," is present in large quantities in women during gestation, and its exact rôle in the physiology of pregnancy has not been determined. Although our attention is necessarily directed to an endocrinologic disorder as possibly responsible for the prolonged retention of a dead fetus and placenta in the uterus, one cannot escape the consideration of a disturbance in the uterus itself as a potential factor.

There is nothing to add to Doctor Slemmons' discussion of the clinical manifestations, diagnosis, and treatment of missed abortion. On the Lane obstetric and gynecologic services, only eleven cases have been indexed under this diagnosis over a period of twenty years. I do feel, however, that the condition is more common than these figures and those quoted by most authors indicate, and we are very grateful to Doctor Slemmons for bringing this subject to our attention.

✽

FRANK W. LYNCH, M.D. (University of California Medical School, San Francisco).—Doctor Slemmons presents a thorough review of this rare condition and illustrates nearly all of its phases with cases from his own practice. His arguments are so convincing that there is very little that a discussor can say. As Doctor Slemmons states, the complication in the past was shrouded with mysticism. Indeed, at one time it was believed that when the woman passed by the threatened abortion and did not extrude the contents of pregnancy, she in all likelihood would not abort until her expected date at term.

Before the discovery of the hormonal reactions of pregnancy, the diagnosis of the death of an early pregnancy was always a most difficult matter. Time in the final analysis gave the diagnosis; yet, when the patient was sick and when it did not seem reasonable to delay treatment more than absolutely necessary, confusion often reigned. It would not seem possible that there might be doubt as to whether the uterus had or had not increased in size from the third to the fourth month, yet very often there is such doubt. When Chadwick's sign had been present and disappeared, there was more than presumptive evidence that something was wrong. Yet Chadwick's sign very often does not appear until the last months of pregnancy. Even the blue discoloration along the middle of the anterior vaginal wall, extending to and about the anterior cervical lip, may be wanting. Yet, when you inspect the vagina of a woman with a missed abortion of six weeks to two months' standing, you will find it bears but little resemblance to the ordinary uterus of a four or five months' pregnancy.

The symptomatology is very interesting. Many women, but not all, develop malaise and symptoms that suggest protoplasmic poisoning. I have often wondered how many times I have been responsible for symptoms when I introduced doubt into the mind of some of my patients that the pregnancy was not developing. Certain it is that few of my patients were happy or contented while I was watching for definite proof that the case was a missed abortion. It is of interest, also, that the animal that has a missed abortion and absorbs the products of conception seldom, if ever, again becomes pregnant.

✽

NORMAN H. WILLIAMS, M.D. (1052 West Sixth Street, Los Angeles).—The subject of missed abortion is appropriate to a program of this kind; it is too seldom discussed. Medical literature relating to it is surprisingly scant. One who supervises obstetrical patients observes the occasional case, but Taussig's estimate of missed abortions as 10 per cent of all abortions seems high. Presuma-

bly the variable incidence, as stated by various observers, results from the present loose definition. Certainly, a definition dependent upon the time elapsing between the death of the fetus and its expulsion, or removal, from the uterus is uncertain; although this may be an aid to diagnosis. A definition based upon a negative biologic test for pregnancy seems more logical.

As Doctor Slemmons suggests, the probable cause of the inertia lies in the unbalanced hormone production, the stimulus to uterine contractions thus being diminished. In all probability, cases will now be observed more carefully as experimental hormonal study becomes better standardized, and its clinical application made more certain.

In the event of missed abortion quite as much tact and judgment are required in handling the mental attitude of the patient and family, as in the treatment of the obstetrical complication. Carelessness there frequently leads to misunderstanding between the patient and her physician. One plausible reason for dissatisfaction lies in the fact that accurate diagnosis must necessarily be delayed; another relates to the infrequency of missed abortion. The laity is not familiar with such a possibility.

It is sound practice to empty the uterus as soon as the diagnosis is made. Procrastination may lead to embarrassment. In one instance, to my knowledge, missed abortion terminated on a ballroom floor.

THE LURE OF MEDICAL HISTORY†

A RARE BOOK*

REVIEW OF ONE OF THE VOLUMES IN THE GROWING COLLECTION IN THE LIBRARY OF THE LOS ANGELES COUNTY MEDICAL ASSOCIATION: FRIAR BARTHOLOMEW'S ENCYCLOPEDIA, BEST SELLER OF THE MIDDLE AGES

By HYMAN MILLER, M.D.
Los Angeles

"BARTHOLOMAEUS ANGLICUS' *De Proprietatibus Rerum*, 1491." So reads the prosaic index card, but far from prosaic is the story behind this card.

Some time between the years 1200 and 1240 A. D., Bartholomew the Englishman, monk of the Franciscan Order, set himself to the task of writing a comprehensive encyclopedia of contemporary lore. Thus was a medieval best-seller born. Busy pens—for this was before the day of the printing press—turned out copy after copy in Latin, Italian, French, Provencal, English, and Spanish. *De Proprietatibus Rerum* (On the Properties of Things)—for such was the name of this book—must have had great popular appeal, for only so can we explain its many translations into vernacular in a world where Latin was the language only of scholars. And only so can we explain the flood of editions which poured forth once 1440 had arrived and Gutenberg had invented printing and the necessary press.

The first printed edition, a Latin one, appeared at Basel about 1470, and by the beginning of the sixteenth century the presses had poured forth nine more Latin, five French, one Dutch, one English, and two Spanish editions. Thus from

†A Twenty-Five Years Ago column, made up of excerpts from the official journal of the California Medical Association of twenty-five years ago, is printed in each issue of CALIFORNIA AND WESTERN MEDICINE. The column is one of the regular features of the Miscellany department, and its page number will be found on the front cover.

* Reprinted from the Bulletin of the Los Angeles County Medical Association.

1470 to 1501, in the first half-century of printing, Bartholomew was represented nineteen times. Not a great number in the 28,000 editions of Incunabula or Cradle Books, but sufficient to entitle him to a place as one of the most popular writers of his time. Nor did his popularity then wane, for by 1582 fifteen more editions of the *De Proprietatibus* had appeared, making, all told, thirty-four printed editions over a period of three centuries, certainly a best-seller, outshining even our modern best-sellers. Incidentally, the last complete edition, an English one, appeared as late as 1907, and as recently as 1933 the *De Proprietatibus* was the subject of a long essay in one of our contemporary journals.

When Doctor Vollbehr, best remembered as the man who amazingly sold the United States Government a million dollars' worth of Incunabula, came to Los Angeles, he was visited by Doctors Dock and Belt and the librarian to see his collection, with the result that the monk, Bartholomew, is now represented on the shelves of our library by a copy of his *De Proprietatibus Rerum*, printed in 1491, and containing Doctor Vollbehr's bookplate of his *Inkunabel-Sammlung*. This Incunabulum takes its place alongside the only other in our library, the *Divinarum Institutionum*, by Lactantius, presented by our friend of San Francisco, Dr. Chauncey Leake.

To bibliophiles, the presence of these books gives a sense of completeness heretofore lacking in our library. To explain this would mean a discussion of the significance of Incunabula in the history of books and all that the word "books" implies. It will suffice to briefly outline what thoughts our copy of the *De Proprietatibus* arouses on being lifted from its protective casing. Despite the suggestion of fragility which this casing and the knowledge of its 446 years of age bring forth, it is a good, sturdy, substantial book, as it had to be when it was loaned out to medical students for a set fee, as was done in the medieval precursors of our modern lending libraries. The binding is of vellum, an ancient Latin leaf from some ecclesiastical manuscript, covered with carefully formed characters and decorated initial letters in still brilliant blue and red. On opening the book there is no title page; instead, on the last leaf there is the printer's colophon, which in those early days of printing performed the same function as our modern title-page. Here we find that the book was printed by one known as George Husner in 1491 at Strassburg, or Argentine as it was then called; that the title of the book is *De Proprietatibus Rerum* and the author, Bartholomaeus Anglicus, Ordinis fratris minor. Turning back to the fly leaf we find written thereon in browned ink, "Ex Libris, Ivan Paul Kaid, M. D. 1659." Who was Doctor Kaid?

Turning the page, we reach the table of contents and here we search for some insight into the character of the author and the reason for the popularity of his writing. We see that he has divided his book into nineteen chapters as follows:

1—On God, 2—On Angels, 3—On Rational Animals, 4—On Body Substance, 5—On Man

and His Parts, 6—On Ages, 7—On Diseases, 8—On Earth and Heaven, 9—On Time and Its Subdivisions, 10—On Elements, 11—On Air, 12—On Birds, 13—On Water and Fishes, 14—On Earth and Its Regions, 15—On Countries, 16—On Stones and Metals, 17—On Herbs and Plants, 18—On Animals, 19—On Music, Colors, Hunting.

On leafing through the book we find the text in Latin, arranged in well-printed double columns of Gothic type. Written in a concise yet readable style, interspersed with touches of dry humor and homely comments on everyday life, it is not to be wondered that edition after edition was necessary to satisfy the reading hunger of a populace just beginning to loosen its belt after the mental famine of the Dark Ages.

Lack of space does not permit a more detailed description of, or comments on the character of Friar Bartholomew's encyclopedic knowledge. Even in the thirteenth century his Chapter 7, *On Diseases*, was a bit behind the times. His discussion of catarrh, sneezing, difficult breathing, phthisis, and quotidian fever were somewhat dated, but then, what text is not, even in these days of rapid communication and ceaseless turning of the presses?

Bartholomaeus Anglicus' *De Proprietatibus Rerum*, 1491, rests on our shelves, fit subject for bibliophilic gossip. May its tribe increase.

1136 West Sixth Street.

CLINICAL NOTES AND CASE REPORTS

CONTRACTION RING DYSTOCIA: TREATMENT WITH EPINEPHRIN

REPORT OF CASES

By BENJAMIN BAKEWELL, M.D.
Santa Barbara

TWO patients, suffering from contraction ring dystocia, are here reported:

CASE 1.—Mrs. C., age 23, a healthy young primipara with history and physical examination negative, missed her period in November, 1933, and went through a normal and uneventful pregnancy. She went into labor July 28, 1934, and accomplished a normal delivery twenty-four hours later after a second stage of only thirty-five minutes. She received pentobarbital and scopolamin in the first stage and gas-oxygen in the second. Her labor developed slowly but normally, and her expulsive pains were regular, strong, and effective.

After the delivery at 3:36 a. m., it was noted that there was exceptionally little blood loss. While waiting for the delivery of the placenta a second-degree episiotomy was repaired, and immediately thereafter, at 4 a. m., an unsuccessful attempt was made to deliver the placenta by the usual methods, and one ampoule of pituitrin was given. At 4:35 a. m., one hour after the delivery of the baby and after a number of futile attempts to deliver the placenta, a manual extraction was attempted and one hand was passed through the dilated cervix into the uterus. The condition there encountered was strange and unusual to a degree. The hand easily entered the cervix, but instead of passing up into the open uterus, it encountered a funnel of contracting uterine wall ending in a tight rigid ring through which it was impossible to introduce even a finger. It was at once evident that here was a typical hour-glass contraction of the uterus.

COMMENT

The problem then immediately developed itself:

What measures must be taken to get past the obstruction and deliver the placenta? A contraction ring always develops below or around some object, whether it be the child's body or the placenta, and the danger to the mother lies, not in the ring itself, but in the necessity for the removal of that which cannot be allowed to remain in the uterus.

The first question was, is this an immediate emergency? Must something be done without a moment's waste of time? The answer was, no. There is perhaps only one purely obstetric third-stage emergency which must be acted upon immediately, and that is hemorrhage. In this case there was not only no hemorrhage but, as already stated, there was less than the normal amount of bleeding. I must confess here that my memory did not bring to mind any routine, usually effective method of relaxing the contraction, and my first reaction was that I was facing the necessity of forcing my way through the ring. This procedure must be undertaken after preliminary attempts at relaxation with deep anesthesia, morphin and atropin, and I visualized, of course, all the possible complications of such an undertaking—shock, hemorrhage, infection, or possibly even rupture of the uterus—and was appalled at subjecting my patient to this experience, normal and uncomplicated as her labor had been up to this period. It was then suggested that epinephrin might be tried to bring about a relaxation of the contraction, and 10 minims was given hypodermically and repeated fifteen minutes later. The hand was again introduced into the uterus, and the ring was felt to slowly give way under moderate pressure. The hand finally slipped through and an adherent placenta was encountered. This was detached by gently slipping the fingers under the adhesions, and delivered. The puerperium was uneventful, and the mother and her child were discharged two weeks later in normal condition.

A review of the literature at my disposal was then undertaken to determine what procedure was advised to be followed in hour-glass contraction. De Lee's "Practice of Obstetrics" cannot be found to more than mention this condition, citing it as a cause of postpartum hemorrhage. No suggestions are given as to its etiology or treatment. However, in discussing tetanic or Bandl's ring contraction about the infant, deep anesthesia and possibly cesarean section is advised.

"Gynecology and Obstetrics" by Curtis, published in 1933, is equally sketchy in regard to hour-glass contraction. The condition is mentioned as occurring, and deep ether anesthesia is advised. In discussing Bandl's ring contraction, deep ether anesthesia is suggested. It states that spinal anesthesia has been tried with good results, and quotes Rucker as saying that five minims of adrenalin may be effective.

I was unable to find any reference in any of our magazines for the last five years to hour-glass contraction, but did find several pertinent articles in regard to Bandl's ring contractions and allied conditions, all, however, very recent.

Dr. Pierce Rucker was evidently the first to suggest the use of adrenalin in contraction ring dystocias. He published an article in 1927 wherein he reported two cases in which the spasm was relaxed by the injection of five minims of adrenalin. He suggested that the spasm is caused by stimulation of the bulbo sacral nerves, while the relaxing mechanism is controlled by the sympathetic fibers. It is these latter that are stimulated by adrenalin. In 1923 Urner reported a case of uterine inversion in which the resultant cervical and uterine spasm was relaxed by gas-ether anesthesia, atropin sulphate, grain 1/150, and one-half cubic centimeter of adrenalin solution. The relaxation was sufficient to permit the inversion to be relieved.

The physiological action of epinephrin is of interest in this connection. Adrenalin is said to affect the plain muscles through stimulation of the sympathetic fibers, so that the result of its action depends upon whether these fibers produce contraction or relaxation. The well-known clinical effect of contracting the skin arterioles, as in the treatment of urticaria, or relaxing the bronchial tree, as in the treatment of asthma, are cases in point. Epinephrin also relaxes certain spasms of the intestinal tract. There is apparently still some confusion as to its exact effect on the muscles of the uterus, but the preponderance of opinion is that this effect is to relax them.

In 1930 Rudolph and Ivy published an article on the physiology of the uterus in labor of the dog and the rabbit. They studied the effect of various drugs on the uterus of these animals while pregnant and during labor, and concluded that, experimentally at least, epinephrin abolishes temporarily the spontaneous activity of both the pregnant and nonpregnant uterus of the dog *in situ* and also the activity excited by the use of pituitrin and ergotamin.

In another article, published by Ivy, Hartman and Koff in 1931, on the contractions of the monkey uterus at term, it is stated that pituitrin causes spastic contraction over the entire uterus followed by intermittent contractions without full relaxation, while epinephrin causes a primary contraction followed by temporary relaxation. They also state that epinephrin abolishes the contractions due to pituitrin and ergotamin.

The second case of contraction ring was encountered in a patient of Dr. William E. Johnson, and was as follows:

CASE 2.—Mrs. L. S., age 30, gravida three, para one, gave a history of having had a tubal pregnancy with operation seven years ago, and one induced abortion. Her last menstruation occurred May 17, 1934, and she went through a normal pregnancy, going into labor at 8 a. m. January 29, 1935, about three weeks before term. The membranes were ruptured artificially at 11 p. m., and at 12:50 a. m. she received quinin sulphate, grains ten, to stimulate lagging pains. She also received nembutol and hyoscin in the first stage. Finally, instrumental delivery being indicated, Kielland's forceps were applied under gas-oxygen anesthesia and the head delivered. Some difficulty was encountered in delivering the shoulders, as they seemed not to come down properly, but they and the arms were finally delivered. From this point no more progress could be made, even with repeated strong traction. This appeared, on the face of it, to be a strange dilemma. The large head, the slightly smaller shoulders, delivered and

yet the body, pelvis and legs resisting delivery. The only possible explanation seemed to be a large fetal tumor. External palpation did not furnish any clue.

The next step to be taken was to explore as thoroughly as possible the cavity of the uterus and the retained portion of the child, and for this purpose the hand was slipped with considerable difficulty up along the baby's body until the fingers reached the level of the lower border of the ribs, where there could be felt a resistant band of hard contracted muscle about the body through which it was impossible to pass more than the tips of the fingers, and this only by depressing the soft tissues of the infant. Again it was evident that we were confronted with a contraction ring. One cubic centimeter of adrenalin was given at once, and a few moments later, with traction on the head and shoulders, the child slowly delivered. The infant was found to be an ascitic monster, with an abdomen measuring 40 centimeters in circumference and with a double hydronephrosis, and it was this distended abdomen that was caught behind the contraction ring.

Here again epinephrin seems to have been the instrument by which a serious situation was changed into one of very little moment.

COMMENT

These two cases are reported that we may call attention to the use of epinephrin in contraction rings; but they may also be used to bring out another suggestion. It would seem to the author that we are too prone to force the uterus in situations where, unknown to us, the unconscious nervous mechanism seems to realize that further expulsive effort may be useless or dangerous.

In the first instance, the very common practice of administering pituitrin in the third stage probably precipitated the contraction ring spasm in a uterus containing an immovable adherent placenta; while in the second case the laboring, overloaded uterus was whipped into a spasm with quinin. Neither of these labors were long nor exhausting, as is usually the case where a contraction ring develops; so that it seems reasonable to lay the blame on the oxytoxics for these two cases of contraction ring dystocia.

1421 State Street.

PHARYNGO-ESOPHAGEAL DIVERTICULUM

By JOSEPH E. TILLOTSON, M.D.
Woodland

DIVERTICULUM of the pharynx is an acquired hernia of the mucosa and submucosa, between the fibers of the inferior constrictor muscle of the pharynx or between the fibers of the cricopharyngeus. The pouch develops in the middle part of the posterior wall. Anatomically the pouch is of pharyngeal origin, but its symptoms are referable to the esophagus which is stenosed through compression by the pouch.¹ The first case of this type was reported during the time of William Hunter, and the specimen is still preserved in the Hunterian Museum, Glasgow.² Since then cases have been reported at different times, though the lesion would seem to be relatively uncommon. In a collected series of 878 patients suffering from pharyngeal or esophageal lesions,

Fig. 1.—V. S. P. Age 59. Large pharyngo-esophageal diverticulum filled with barium mixture. It is directed toward the right side and extends into the upper mediastinum. There were marked symptoms; return of undigested food, delayed swallowing, paroxysms of coughing, and dyspnea.

McMillan³ reported 3 per cent as pharyngeal diverticula. Carcinoma of the esophagus, the most common type lesion in this group, was ten times more frequent than the diverticulum.

REPORT OF CASE

V. P. S., male, age fifty-nine, was admitted to Yolo County Hospital, Woodland, California, January 25, 1936. Symptoms were of eight years' standing, and developed gradually until the last six months, when they progressed rapidly and became marked. The first difficulty noticed was that food seemed to catch on swallowing. Undigested pieces of food often returned into his mouth involuntarily. Other people would finish a meal, while he would only begin to eat. During the last six months there were frequent paroxysms of coughing and dyspnea. The patient lost weight; became apprehensive; was fearful of going to sleep; deliberately lived near an emergency hospital, where he might receive hypodermic injections of adrenalin, which temporarily relieved the asthma-like paroxysms of cough and dyspnea.

A nontender fullness in the lower right side of the neck was palpable; at times it changed in size. A barium film showed a well-defined pouch directed toward the right and extending into the upper mediastinum, shown in Figure 1. Dr. R. S. Tillotson examined the patient with esophageal speculum and reported the mouth of the diverticulum was entered by the instrument without difficulty, and that the subdiverticular opening of the esophagus was identified anteriorly.

At operation the anesthetic used was evipal intravenously. Preliminary to this a small rubber tube was passed through the nose to the stomach. An incision was made along the anterior border of the sternomastoid muscle, from the superior border of the thyroid cartilage to the suprasternal notch. The anterior jugular vein was ligated; the deep cervical fascia was divided; then the omohyoid muscle divided; the thyroid and larynx retracted medially, and the carotid vessels laterally. The sac was fairly easy to identify, as it came out from between the esophagus and the bodies of the lower cervical vertebrae toward the right and into the upper mediastinum. It was freed to its junction with the pharynx. When isolated, to the touch it felt very much like a normal gall-bladder and had a somewhat similar gross appearance. Since the pouch went fairly well into the

mediastinum it was thought best to remove it by two stages. In doing this the general plan outlined by Lahey⁴ was followed. At the first stage, the sac was anchored in the upper angle of the wound. Iodoform packing was inserted below. When the margins of the wound came together, about one inch of the pouch projected beyond the surface level of the skin. At the end of ten days, during which time the wound granulated in, the second stage of the operation was done under evipal anesthesia, and supplemented by a small amount of ether by inhalation near the end of the procedure. During the period between the stages of the operation the patient was fed by a small naso-stomach tube. At this second stage operation, the wound was opened at its upper angle and the sac isolated. To the writer the sac wall seemed thinner than at the first operation. Before the first-stage operation the pouch, over a long period of time, was under considerable distention and irritation by food. The period of rest, through the use of the naso-stomach tube, evidently allowed edema in the pouch to subside. The sac was ligated and excised at its neck, and interrupted sutures through remnants of fascia overlapped the pedicle. A small iodoform pack was inserted into the wound, and it was allowed to heal by granulation. Use of the naso-stomach tube was continued for five days. A fistulous tract resulted in the wound, from which small amounts of fluid and food were expelled with swallowing; but this tract completely closed by the tenth day following the operation.

There was complete relief of symptoms by the operation. The patient ate ravenously and gained ten pounds in two weeks. Difficult swallowing, cough, and dyspnea completely disappeared.

COMMENT

The writer has described a large pharyngo-esophageal diverticulum with marked symptoms. It was operated on with dramatic relief of symptoms. According to the recorded cases of these diverticula reported, the great majority protrude to the left, but this one protruded to the right. The large size of the sac facilitated its isolation. The sac was more thick-walled than might be expected. Microscopic study showed considerable muscle in its wall, which doubtlessly was an hypertrophy due to the long duration of food irritation and recurrent emptying. The sac extended well into the upper mediastinum, and this prompted a two-stage operation as a safeguard against mediastinal infection. There was not primary union following excision of the sac, but the fistulous tract healed without undue delay.

Yolo County Hospital.

GONORRHEAL TENOSYNOVITIS

By JAMES E. REEVES, M.D.
San Diego

IT can be assumed that gonorrheal infections of tendon sheaths are comparatively rare, as no mention of this complication is made in any of several standards works on urology consulted.

An occasional report appears in the literature; one case by Hayward,¹ and another by Murray and Morgan,² in which incision over affected tendon was productive of pus containing Gram-negative intracellular diplococci, morphologically *N. gonorrhea*.

⁴ Lahey, Frank H.: *The Surgical Management of Pharyngo-Esophageal Diverticulum*, Surg., Gynec., and Obst., 51:227-236 (Aug.), 1930.

¹ Hayward, H.: *Gonorrhea of Tendon Sheaths*, Medizinische Klinik, 27:1683, 1931.

² Murray, D. W. G., and Morgan, J. R. E.: *Gonorrheal Tenosynovitis of the Hand*, Canad. M. A. J., 32:374 (April), 1935.

Gonorrheal tenosynovitis of the long head of the biceps was diagnosed by Zadek³ by means of stained sections of tissue, removed by operation.

There is no doubt that this complication has been observed by others and not deemed sufficiently important to report.

REPORT OF CASE

F. J. M., Corporal United States Marine Corps, white, male, age 27.

The patient was exposed to venereal disease in San Diego, California, on January 5, 1936, and took prophylaxis aboard his ship about four hours later. On January 12, 1936, he noticed burning and frequency of urination, followed in a few hours by a creamy urethral discharge. Coincident with appearance of the discharge, the patient bruised the dorsum of his right foot. When he reported to the Sick Bay he complained of marked pain in the foot, in addition to a urethral discharge. On admission, January 13, 1936, he presented the following picture: Temperature, 102 degrees Fahrenheit; pulse, 100; R, 18; urine normal; white blood cells, 19,500; bands, 13 per cent; segs., 50 per cent; lymphocytes, 27 per cent; mononuclears, 10 per cent. Smear of urethral discharge revealed many pus cells, many extracellular and few intracellular Gram-negative diplococci, morphologically, *Neisseria gonorrhoea*. Dorsum of right foot was swollen, tender, and erythematous. There was a profuse, creamy urethral discharge.

The patient was put to bed with foot elevated, and application of constant external heat. Anterior urethral irrigations with 1 to 10,000 potassium permanganate solution were begun.

Temperature for the first six days following admission varied from 99 to 102 degrees Fahrenheit, and the swelling and erythema over the dorsum of the foot gradually increased.

On January 19, 1936, a fluctuating area over the first of the four tendons of the extensor digitorum longus muscle was incised and yielded about 15 cubic centimeters of serosanguinous pus. Smear of the pus obtained showed many pus cells, and intracellular Gram-negative diplococci, morphologically *Neisseria gonorrhoea*.

A drain was inserted and radiotherapy treatments were begun and given twice daily, using two large, well-padded electrodes and 2,500 M. A. (resonance control) frequency, for twenty minutes. Following the second radiotherapy treatment (using the De Forrest laboratories' 250 watt 18 meter, 16.3 kilocycles apparatus), most of the pain disappeared.

From the day of admission until healing of the foot was complete, the white blood cell count averaged about 20,000 per cubic millimeter, and there was an increase in the number of segmented leukocytes. Normal total and differential white blood counts were obtained from the time healing was complete until he was discharged. As the drainage from the incision lessened, the daily afternoon temperature gradually became lower and reached normal ten days after incision, where it remained until discharge to duty.

Examination two weeks after discharge: found the urine clear, prostate and adnexa normal, no urethral stricture present, and normal motion present in the foot.

CONCLUSION

1. An unusual case of gonorrheal infection of a tendon sheath is presented.

2. Treatment with high frequency current appeared to limit destruction, relieve pain and facilitate healing.

3. Tendon injuries during the initial stages of gonorrhea may possibly precipitate gonorrheal tenosynovitis.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

PREANESTHETIC DRUGS

I. A PHARMACOLOGIST'S VIEWPOINT*

C. D. LEAKE, Ph.D. (University of California Medical School, San Francisco).—Proper psychic preparation of a surgical patient, by an anesthetist who appreciates something of the psychology of fear and of the means by which the dread of a surgical operation may be minimized, will do much to improve such a patient's general status before the actual anesthetic is administered. But for the average patient, where time is not always available for this procedure, a suitable preanesthetic hypnotic may be necessary to supplement the anesthetist's psychic approach. A preanesthetic hypnotic, however, is not indicated solely for the relief of fear the patient may have for anesthesia; it has a definite function in the actual induction and conduct of the anesthesia. As pointed out so strikingly by Waters and Guedel,¹ such an hypnotic is most useful in lowering the patient's general metabolic level to a point where the anesthetic may be easily and smoothly administered.

Preanesthetic hypnosis certainly reduces the amount of anesthetic agent required, so that during the direct anesthesia more oxygen may be given than would otherwise be the case, were no preliminary depressant agent employed. Thus, with proper preanesthetic preparation, a satisfactory degree of surgical anesthesia may be readily secured even by nitrous oxid and oxygen without pushing nitrous oxid to a dangerous asphyxial concentration, which is frequently necessary without supplementary depression.

Although much general dissatisfaction has been expressed with morphin and hyoscin (scopolamin) as *preanesthetic hypnotics*, they continue to be used quite routinely in the absence of any pressing clinical necessity for something better. Morphin is definitely indicated, of course, as a *preanesthetic analgesic* when pain is present. A consideration of the pharmacology of these agents may be of interest in supporting the independent clinical condemnation of these agents for *preanesthetic hypnosis* years ago by such competent observers as Herb, Gatch, and Bevan.²

The primary effect of morphin is stimulation of the central nervous system, which is promptly masked in humans by a secondary depression. *The stimulating action outlasts the depression.* Thus, after the depression wears off there is increased irritability and cortical excitement, which may be responsible for the initiation of craving

and habit. That is, during the after-period of irritability the individual craves the drug again in order to recover the pleasant euphoria of the depressant stage.³ Another objection to morphin as an adjunct to anesthesia is its tendency to cause constipation, which interferes with a proper post-anesthetic condition. However, the definite stimulation of intestinal musculature by morphin may help greatly in preventing postoperative intestinal stasis.⁴ Furthermore, morphin is not helpful in anesthesia because its action in depressing respiration interferes with the rapidity of absorption or elimination of an inhalation anesthetic. To these three important pharmacologic objections might be added its tendency to disturb carbohydrate metabolism, in a manner not conducive to the best condition of the patient, as reflected in its effect on blood sugar and on the acid-base balance of the blood.⁵ In justice to morphin, however, it should be noted that the clinical opinion, that it interferes with kidney function, has little support when critically examined.⁶ The suppression of renal activity under anesthesia seems to be a reflex effect of irritation of the laryngeal mucous membrane by the anesthetic gases.⁷

There is no doubt, however, that morphin remains the best preanesthetic hypnotic when *traumatic* pain is present. Its amazingly effective action in relieving traumatic pain should not be denied the patient, either before or after the operation, if its use is indicated. The National Research Council is spending a great sum of money annually to finance chemical research at the University of Virginia, and pharmacologic work at the University of Michigan under the direction of Dr. N. B. Eddy, to develop a satisfactory substitute for morphin which will be free from its addiction dangers. The resultant pharmacologic studies are currently appearing in the *Journal of Pharmacology and Experimental Therapeutics*. Meanwhile, a morphin derivative called "dilaudid" was enthusiastically introduced in this country by Alvarez.⁸ Subsequent clinical use has indicated, however, that "dilaudid" has probably the same potential addiction properties as those possessed by morphin. Dr. Norman A. David, formerly of this laboratory, has made an interesting comparison of the two agents.⁹

Little rational evidence exists that opium or a mixture of its alkaloids free from non-alkaloidal material ("pantopon") has any advantage over morphin as a preanesthetic hypnotic. Such a mixture of the differently acting alkaloids in opium is an irrational material to use, since not only aggravation of some of the deleterious effects of morphin, as its constipating action, is known to occur by giving it with other opium alkaloids, but indeed few of these other alkaloids have been properly studied, either pharmacologically or clinically, to know how they may act. Scientific therapy demands the use of chemical agents singly for definite effects, avoiding confusing mixtures of any sort. Certainly, preanesthetic hypnosis should be simplified and rationalized rather than complicated.

If there is pain present due to swelling of tissue, then morphin is not as effective as such drugs as amidopyrin, the salicylates or the cinchophens. These antipyretics exert their pain-relieving action, when pain is due to swelling of tissue, by pulling fluids out of such swollen tissue back into the blood stream, as indicated by the careful studies of Barbour.¹⁰

Hyoscin or scopolamin is said to synergize with morphin, enhancing its depressant action, especially on the cortex. The pharmacology of hyoscin has not been very thoroughly studied, and there seem to be few clinical observations of a critical nature on the effects of this drug in connection with anesthesia. Hyoscin is chemically related to atropin and has a similar effect on the autonomic nervous system. This action, as we shall see, may be detrimental in preanesthetic medication. In the absence of any reliable or critical evidence of its usefulness as a preanesthetic hypnotic, little justification exists for its continued use merely because of clinical habit or routine. There is an opportunity here for clinical judgment to evaluate critically its status as an adjunct to anesthesia. Barlow has recently shown experimentally that hyoscin is of no value in nitrous oxid anesthesia and, indeed, it may be detrimental.¹¹

In the effort to find more satisfactory preanesthetic hypnotics which might be substituted for morphin, a number of other substances were studied in my laboratory from the point of view of their effects on the body functions of normal human subjects, in comparison with morphin.¹² We studied especially the action of these various depressant drugs on basal metabolic rate, tactile discrimination, respiration, pulse rate, and blood pressure. We thought our observation might furnish us with objective quantitative criteria for estimating depressant action of the different drugs on the central nervous system. While codein has much to recommend it over morphin as a central nervous system depressant, it is not sufficiently powerful, in our judgment, to justify its use clinically for preanesthetic hypnosis.¹³

The exploitation of sodium amytal suggested that we study barbitol and its common derivatives from this standpoint. *As a result of our observations on normal humans, we may recommend barbitol by mouth as a possible substitute for morphin as a preanesthetic hypnotic, if no pain is present.* In the average adult it may be expected to bring relief from fear and apprehension, and to dispose toward sleep, relaxation and amnesia, in doses of 1 to 1.5 grams, or even higher. It depresses the basal metabolic rate in the same way as morphin, and is otherwise generally depressing. No residual stimulation results, and the psychic disadvantage of hypodermic administration is avoided. It may sometimes cause a cutaneous rash, however, and it is of no use as a hypnotic if pain is present. Subjective reactions to barbitol vary greatly with physical constitution and social background. If the ordinary local anesthetics are to be used, it is definitely indicated since it protects against their toxic manifestations.¹⁴ With spinal anesthesia, the status of which still remains to be established, more of an analgesic effect is needed in the preanesthetic medication, and morphin or amidopyrin is indicated.

We could not find that phenobarbital, or any of the common commercial modifications of barbitol, including "amytal," "dial," "ipral," "neonal," and "phanodorn," have any significant advantages over barbitol as hypnotic agents in man. Indeed, they all showed some disadvantages.¹⁵ Eddy, however, from animal experiments, believes "amytal" has the greatest depressing effect.¹⁶

It is sometimes amusing to the pharmacologist to observe the enthusiasm with which certain clinicians continue to report experiences with new drugs. There seem to be fads and styles with drugs as with clothes. If medical men generally realized the extent to which preliminary and unconfirmed pharmacologic evidence is distorted by drug concerns (usually foreign) for clinical exploitation of new agents, they would undoubtedly be more reserved in expressing clinical opinions. Very few new drugs reach clinical trial in an ideal scientific manner.¹⁷

Sodium amytal was thus overenthusiastically recommended as a general anesthetic when given in strongly alkaline solution by vein. While the induction of sleep and amnesia is dramatic by this technique, it is obvious that the agent is not in itself sufficiently analgesic to be a satisfactory general anesthetic except in dangerous doses. There is too narrow a margin of safety between the dose causing real anesthesia and that depressing the medullary centers to a lethal level. Sodium amytal thus falls in the class of anesthetic adjuncts, as now admitted by its original proponents.¹⁸ The intravenous, or even oral, use of this

substance as a routine preanesthetic hypnotic is not justified until it has been more thoroughly evaluated in comparison with what, in our opinion, is as satisfactory, and certainly a less expensive official drug, barbital.

A new German barbital derivative, called "evipal," has recently been exploited for intravenous anesthesia. It is subject to the same general criticisms as sodium amytal by vein. It has, however, one advantage in that it seems to be fairly rapidly destroyed in the body, so that recovery from an anesthetic dose is, consequently, rapid.

Stormount¹⁹ and associates have directly studied the preanesthetic value of various barbitals in nitrous oxid and oxygen anesthesia in rats. They found that 85 per cent nitrous oxid with 15 per cent oxygen (enough to prevent anoxemia at sea level) will anesthetize with 30 per cent of the average lethal dose of "dial" and "neonal," but that 45 per cent of the average lethal dose of "amytal," barbital, and phenobarbital is required to give this same effect. In man, however, we found barbital the most satisfactory depressant of the series, in so far as lowering of the basal metabolic rate, dulling of tactile discrimination, and tending toward sleep are concerned. Amytal and phenobarbital, we noted, increased the basal metabolic rate except in high doses. The relative merits of the several derivatives of barbital as preanesthetic hypnotics remain, therefore, to be further evaluated before surgeons are justified in using any of its modifications for this purpose, in preference to the well-studied parent substance, barbital.

It is hardly possible that any of the other multitudinous commercial derivatives of urea exploited so vigorously, especially by the Germans, have any great advantage over barbital in this regard. One of these, "pernocton,"²⁰ includes bromin, which introduces another difficult depressant factor to evaluate. Chemists have sought for some time to develop barbital derivatives which are rapidly destroyed or removed from the body. One of these, "evipal," has already been mentioned. In this country the Lilly and Abbott laboratories developed, almost simultaneously, an identical compound called, by the former, "pentobarbital," and by the latter, "nembutal." These barbitals are relatively short in action, but the effects of repeated administrations must still be carefully studied in order to determine whether any residuum remains which may lead to the danger of chronic poisoning.

Particularly to be condemned are combinations of barbital or its derivatives in fixed proportions with amidopyrin, such as "allonal," "cibalgin," or "pyraminal." Aside from the violation of rational therapy by such mixtures of a hypnotic with an analgesic in fixed proportions without regard to the indications of the individual patient, as scored by the Council on Pharmacy and Chemistry,²¹

Koppanyi and Lieberman²² have shown that the analgesic component of such mixtures is eliminated much more rapidly than the hypnotic, so that grave danger of the cumulative effect of the latter is present if the dose is repeated to get continued analgesic action.

The same general considerations hold for tribrom-ethyl alcohol ("avertin"). Enthusiastically advocated as a general anesthetic by those who hitherto rarely saw good modern anesthesia by gas and oxygen, more critical clinical opinion now recognizes this agent more properly as merely an adjunct to anesthesia.²³ The difficulties of preparation, the dangers of toxic decomposition, the necessary mode of administration and the pharmacologic action of the drug limit its usefulness, as in the case of sodium amytal by vein, to abnormally apprehensive or excited patients, and then in doses not so high as to give partial analgesia with dangerous depression of the vital centers—that is, not much more than 75 milligrams per kilo body weight. It is peculiar that physicians should become so excited over tribrom-ethanol by rectum, when paraldehyd, a much cheaper and safer drug, was used in this manner as a preanesthetic agent many years ago. The enthusiasm over tribrom-ethanol has revived interest in paraldehyd as a safe and effective preanesthetic hypnotic.²⁴

The prolonged action of tribrom-ethanol and of the barbitals, especially sodium amytal by vein, may have a useful postoperative effect in keeping the patient quiet and asleep. But often with the barbitals motor excitement may supervene, especially if large doses are used, and contrariwise, if the dose is too high, such severe depression may result that constant attention is needed to prevent accidental asphyxiation or other complications.

The central nervous system depressant action of magnesium sulphate and its dramatic antagonism by calcium chlorid were demonstrated experimentally by Meltzer and Auer²⁵ in 1908. Clinically developed by Gwathmey²⁶ for aid in preanesthetic hypnosis, its possible field of service has become somewhat neglected in the undignified rush to help exploit the newer commercialized drugs. The characteristic feature of its action is depression of motor tone and activity, so that it would seem to be especially indicated in patients with motor excitement or with so much muscular tone as to interfere with satisfactory surgery. One or two cubic centimeters of a 50 per cent sterile solution injected intramuscularly is an average dose for this effect. It is claimed that the drug synergizes with morphin and the general anesthetics, so that care must be observed in its use with these agents.

Atropin was introduced as an adjunct to chloroform anesthesia, in order, by paralyzing the pe-

ripheral endings of the vagi, to prevent reflex stoppage of the heart during the induction stage. With ether anesthesia it is advocated on the basis of preventing the "mucous inundation" caused by the irritant action of ether vapor on bronchial mucous membranes, and/or suppressing salivation. With modern gas-oxygen anesthesia, especially when the excellent rebreathing technique devised by Waters is used²⁷ (in which every aspect tends so nicely to conserve the physiologic balance of the patient), these excuses for the use of atropin do not exist. This drug should certainly not be used routinely.

Osborne points out²⁸ that it is not good practice from the standpoint of physiology to interfere with the protective function of bronchial secretion, as long as satisfactory cough reflex is present to prevent the formation of mucous plugs with the danger of resultant atelectasis. The bronchial and intestinal relaxation induced by atropin cannot be considered beneficial to the postoperative condition of the patient. Atropin further tends to cause some cortical stimulation, and surely the dryness of the mouth it produces is no joy to the patient already thirsty in the usual postoperative state. Atropin, therefore, in my opinion, should be reserved for use when specially indicated, as in chloroform or extensive ether anesthesia, or when there is reason to expect an embarrassing mucous or salivary secretion during the operation.

In conclusion, routine preanesthetic medication is to be strongly condemned. So also is an undignified rush to aid the clinical exploitation of new commercial agents not yet properly evaluated pharmacologically. Each patient should be separately considered, from the standpoint of preanesthetic hypnosis, with regard to type of chemical agent to be employed and, if necessary at all, dosage and mode of administration. The clinical evaluation of new agents should be left to university or research hospitals, where critical study with proper control methods are most likely to be found.

* * *

II. AN ANESTHETIST'S VIEWPOINT

MARY E. BOTSFORD, M. D. (807 Francisco Street, San Francisco).—The selection of the drug and estimation of dosage are of as much importance in producing and maintaining safe and efficient anesthesia as the agent employed and the method of administration. Modern medicine requires that the patient come to the operating table in the best attainable physical and psychic condition. Where formerly the choice was limited to a few hypnotics, pharmacologic progress has increased their number so that it is now possible to fill the need of the individual case.

The various forms of *opium* have not so far been superseded by any of the newer discoveries, but its action may be assisted and modified by such adjuvants as the barbiturates, tribromethanol,

evipal, paraldehyd, etc. According to Hewitt, idiosyncrasy to morphin exists in only 2 per cent of cases. It is more frequent in the *barbiturate group*. With the latter it is possible, in adults at least, by giving a minimal dose the night before operation, to establish the individual reaction, and the preanesthetic dose may be prescribed accordingly. The great value of the barbiturates lies in their hypnotic effect and, if given at least an hour before operation, they prevent the frequent stage of excitement which, by accelerating cardiac and respiratory action, lengthens the period of induction and necessitates the use of a greater amount of the anesthetic agent. When followed by morphin or pantopon, a quiet induction and smooth maintenance of inhalation anesthesia are ensured.

Avertin is of value in apprehensive patients and many minor operations, as well as brain surgery, where inhalation anesthetics increase hemorrhage, may be performed under its effect without further anesthetization. The addition of atropin to the dose of morphin is a routine procedure, which is strongly to be condemned, notwithstanding the fact that a large majority of the adult patients operated in this country are premedicated with a one-sixth to one-quarter grain of morphin and 1/150 to 1/120 grain of atropin. There has not yet been discovered a better preanesthetic drug than morphin, but the addition of atropin often nullifies its benefits. Atropin is the physiologic antagonist of morphin, whose sedation—psychic, cardiac, respiratory, and secretory—is of the utmost value in producing and maintaining efficient and safe anesthesia. The purpose of atropin is said to be its action on salivary glands, and if given alone it does decrease secretion; but with any form of opium it overcomes the effect of the latter in controlling mouth secretions. Further, its stimulating effect upon respiration is a definite disadvantage, particularly in abdominal surgery; the increased diaphragmatic activity interfering with intestinal relaxation, resulting in the necessity for producing too deep anesthesia.

Ether is in itself a cardiac and respiratory stimulant. The gaseous anesthetics, nitrous oxid, ethylene, and cyclopropane have little effect on cardiac and respiratory functions, when anoxemia is not present. The only logical place for atropin is in chloroform anesthesia, where respiratory stimulation is necessary.

Scopolamin, which fell into disfavor some years ago because of deaths resulting from an impure product, is being much used in combination with morphin. Sollmann finds it sedative in all doses, while even moderate doses of atropin are excitant.

Protection of the psyche from distressing mental impressions is of even greater importance in children than in adults. Psychiatrists and psychologists have demonstrated abundantly the evils, often developing years later, of mental complexes definitely traced to early impressions caused by fear, and there is no more potent factor in its production than the dread of operation, the awe-inspiring preliminaries, and the often forcible administration of anesthetics.

²⁷ Waters, R. M.: Arch. Surg., in press.

²⁸ Osborne, W.: Lecture on Surgical Applications of Physiology, San Francisco, 1930.

The addition of the barbiturates has helped immeasurably in providing an escape from the depressing effect of fear by influencing the nervous system sufficiently, when administered preanesthetically, to produce unconsciousness, or at least indifference to the sights and sounds incident to transportation to the operating room and the induction of anesthesia. The mass of evidence available in the literature, based on research conducted by pharmacologists, anesthetists, and surgeons, has proved conclusively the value of the barbiturates.

Determination of the drug and dosage should depend not only upon the kind of operative procedure, but the age, physical and mental condition of the patient.

* * *

III. A SURGEON'S VIEWPOINT

JOHN HOMER WOOLSEY, M. D. (Woodland Clinic, Woodland).—The use of preanesthetic drugs, in the opinion of the majority, marks great advancement in the medical science because of the additional comfort and care they afford our surgical patients. As human beings endowed with comprehending minds, we reason and thereby suffer mental as well as physical injury. To the average patient there is nothing more important than the anesthetic because of the fear of giving up control of the vital processes. Preanesthetic drugs, when properly used, eradicate fear and assist in mental and physical rest. They help prepare the patient to undergo the necessary physical effort of any surgical procedure.

Safety to the Patient

The safety of the patient is always the paramount factor. Preoperative drugs should not be so powerful as to prevent the anesthetic agent from being the controlling factor. When seen in the operating room, it is true that the effect of a massive dose of preanesthetic medication generates enthusiasm, but its complications and sequelae, when observed in the postoperative period, dampen this enthusiasm.

The desired effect of preoperative medication is to quiet the patient, to eliminate apprehension, to enable the general anesthetic agent to control the patient's respiration and final relaxation, and to assist in a prompt postanesthetic recovery. How are we to obtain these?

In the first place, standardization of preanesthetic medication is impossible. It is an individual problem. Not only body weight, but age, sex, degree of nervousness, metabolic rate, and temperature are influential factors. A patient's susceptibility must, therefore, be individually estimated. This can be done by the use of divided dose—that is, a portion the evening before and another portion preoperatively the morning of the operation. Observance of the patient's reaction to a preanesthetic drug given the previous evening will more accurately determine the amount for immediate preoperative medication.

The postanesthetic recovery of a patient should be sufficiently prompt to allow voluntary response within one hour. Prolonged depression leads to

retained secretion in the respiratory system and a greater tendency to partial pulmonary collapse. Instances of the dropping back of the tongue, with obstruction of the glottis and the interference of respiration, have been reported. It is also desirable to have the patient's cooperation in remaining covered, and in the administration of parenteral fluids.

Influential Factors

Body weight is the most important influential factor in determining the dosage of the preanesthetic drug. Heavily muscled individuals, such as athletes and workmen, demand more drugs than those whose weight consists of a considerable degree of fat.

Age is of importance, since under twelve years and over sixty years, the barbituric acid derivatives do not have a uniform effect and afterward are too depressive. Also in the aged, certain forms frequently stimulate unpleasant dreams and fearful memories, and in those suffering from cerebral disease toleration of these drugs is poor.

Because of its importance, let us reiterate, much depression of the respiration in the very young, the old, and in those with cerebral disease occurs with the preanesthetic drugs, and they must be used, therefore, with caution. In children drugs by mouth are not always readily absorbed, and rectal administration is often disturbing and occasionally expelled.

Sex plays a part chiefly because of the increased musculature of the male which demands, accordingly, more or less of a drug. There is a question in regard to the advisability of preanesthetic drugs in the cesarean section, for there should be no handicap to the respiratory efforts of the baby; and although many employ a barbitol or morphin and claim no disturbance, others report instances of a definite depressive effect upon the baby.

Apprehension attendant upon an operation demands more sedation. A patient who has previously experienced the effect of preanesthetic medication has a certain amount of anticipation with the second administration, and will be more resistant to the same amount of the drug.

An increased metabolic rate and fever—some-what similar factors, for they produce a more rapid absorption and elimination of any drug—demand a greater dosage. For example, in thyrotoxicosis the average dosage will produce inebriation rather than the desired drowsiness.

Choice of Medication

It is a known fact that the preliminary hypodermic of morphin, in the dosage of .015 to .01 gram (one-quarter to one-sixth grain) is of benefit; but there can be discussion as to the merits of pantopon, dilaudid, and scopolamin.

Pantopon supposedly depresses respiration less in relation to its narcotic activity, produces vomiting less readily, has less prolonged action, and is less euphoric than morphin. It has not proved to be as uniform in action and, as Barlow states, "it is not believed to have as *tranquilizing proper-*

ties as morphin." Collins of Chicago, on the other hand, is of the opinion that pantopon is a better drug than morphin. Personally, our experience is similar to that of Barlow.

Dilaudid, which is a quite commonly used drug in place of morphin, has an equal amount of narcotic effect, is excellent for routine use in relief of pain, but does not possess the desired preoperative hypnotic action.

Scopolamin (hyoscin) has no sedative effect, but does have an amnesic or disorientation phenomenon. It is this author's experience that, in the aged, this drug has been quite disturbing because of stimulation of unpleasant dreams and fearful memories. In children and adults it has a place, for it combines, with the above-mentioned effects, a depressant to the salivary and mucous secretions. Leech of Regina, Canada, recommends its use in small doses in addition to morphin, especially for children.

Tri-brom-ethyl alcohol (avertin) has a hypnotic, rather than an anesthetic effect, and it is recommended that it should be used only as a hypnotic in the production of "basal anesthesia." When used in too large a dosage, it carries with it the danger of losing the paramount factor demanded in anesthesia—the control of the patient. The demands made in the administration of this drug are comparatively great, and the period of postoperative recovery is prolonged, requiring increased nursing care. Supplemented with local anesthesia, this drug appears today to be the choice for brain surgery. In such cases, a long operation and special nursing care are the rule; but the operation, while meticulous, is not as shocking as the average celiotomy. In its favor are its complete elimination of psychic trauma, its lack of accompanying or subsequent nausea and vomiting, and its rare pulmonary sequelae. Against its use is the great potential danger to the safety of the patient in the loss of control by the attending physician or surgeon.

The *barbituric acid* hypnotics have demanded an increasing interest during the past fifteen years. There is a unanimity of opinion that oral or rectal administration is preferable and is sufficient, provided there can be an interval of three-fourths of an hour before operation. The intravenous method has too narrow a margin of safety. There is also confusion as to the best form of this drug because of the variation of hypnotic efficiency, the rate of oxidation and the speed of elimination which these barbituric acid combinations possess.

From the data available concerning some of the forms, the following facts have been determined:

Di-ethyl barbituric acid (barbital), 25 to 30 per cent, is used, is absorbed slowly, and 70 to 75 per cent is eliminated over seven to eight days.

Phenyl-ethyl-barbituric acid or phenobarbital (luminal) 80 per cent is used, is absorbed slowly, and the 20 per cent eliminated appears as late as the tenth day.

Allyl-iso-propyl barbituric acid (allonal) 80 per cent is used, is absorbed at a moderate rate, and all is eliminated by twenty-four hours.

Sodium iso-amyl-ethyl barbituric acid (sodium amytal) no definite data is available; but in comparison with phenobarbital, it is absorbed more rapidly, and has a greater and longer hypnotic effect, lasting up to ten hours.

Sodium ethyl-methyl-butyl barbituric acid or pentobarbital sodium (nembutal) no definite data is available, but in comparison with all other barbiturates it is rapidly absorbed, has a greater hypnotic and a less-prolonged effect, which is over, on the average, of four hours.

The more rapid the absorption the greater is the hypnosis, and the more rapid the elimination the quicker the recovery. Therefore, we can, with some scientific precision, choose the barbituric derivatives best adapted to the type of patient and operation. In order to assure the patient a restful night, preoperatively, sodium amytal or sodium pentobarbital are most universally satisfactory, since they are absorbed quite completely at a moderate rate and eliminated within eight to ten hours. For the immediate preoperative use, a rapidly absorbing form (greater hypnotic power) is advisable, and sodium pentobarbital (nembutal) is the choice. For prompt postoperative recovery a quickly eliminated form should be used, and we believe sodium pentobarbital (nembutal) gives the best results.

A most satisfactory hypnosis and prompt postoperative recovery are secured when sodium amytal is given the previous evening and, according to the patient's response, a dose of pentobarbital sodium is administered one and one-half hours before operation.

Personally, we believe the barbituric acid derivatives are the most practical and the safest drugs. For preanesthetic medication we employ sodium amytal .18 gram (grains iii) or pentobarbital sodium .09 gram (grain iss) orally the evening before operation, and pentobarbital sodium (nembutal) .09 gram (grain iss) one and one-half hours before surgery, with a hypodermic administration of morphin .01 gram (one-sixth grain) and atropin .004 (1/150 grain) one-half hour before surgery. Our experience has been similar to Barlow and his co-workers, who report that 68 per cent are drowsy and uninterested in any procedure, 24 per cent asleep, and 8 per cent inebriated and move slightly when disturbed. As previously stated, the aged do not stand barbitals well; yet, recently, pentobarbital sodium—possibly because of its relatively rapid absorption and elimination—has given us the desired effect without as much mental disturbance as with the use of other barbitals.

Conclusions

One's opinion, influenced by his experience, changes from year to year; therefore, the combined opinion of the profession on this problem is desired. It seems wise to select a combination of agents for complete elimination of psychic trauma, physical relaxation and freedom from pain, without depression of the patient's vital functions, but with control of the patient during the preanesthetic, anesthetic, and postanesthetic stages.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6.

ASSOCIATION ACTIVITIES

AMERICAN MEDICAL ASSOCIATION FELLOWSHIP

At the beginning of a new year it is timely to once more urge members to make application for fellowship in the American Medical Association. Our national organization performs a very tremendous amount of service for the profession as a whole as well as for every member. This service is related to national legislative matters and our relationship to the public and public activities related to health welfare and medical service.

There are twelve bureaus and councils with full-time directors or secretaries, located in the headquarters building in Chicago, and they, with the general officers and some seven hundred employees, are continuously and persistently engaged in work that concerns every doctor of medicine. Without that service our profession could not maintain the position and standing that we now hold. Without that service and alertness we would be the pawns of designing propagandists and those who are inspired by selfish and ulterior motives and quests. Our national association renders a very distinct and personal service to every doctor of medicine. It merits the support of every practitioner. That support is subscribed by becoming a Fellow of the American Medical Association. Are you rendering that support?

To become a Fellow you must make a special application through your State Secretary. Your membership in your county and state association does not carry or automatically convey to you American Medical Association Fellowship. Special application must be made as indicated above. Send in for an application blank today.

The annual fellowship dues are \$7. In return for these dues, you receive the benefits of representation and, in addition, the weekly issue of the *Journal of the American Medical Association*. Valuable as this journal has been, it is going to become more valuable by reason of a new department or section on medical economics that was added at the beginning of January. This new section will present information related to the Security program, federal legislation, and social movements—questions that are

receiving widespread attention in Washington and in every state.

Hence, the recommendation that you apply for fellowship and lend support to these activities that are so vital to your future.

WHO KNOWS BETTER?

An institution's medical director was conducting a few visitors through his sanitarium for mental cases. He paused before one patient, and asked: "John, why do you insist on scratching yourself?" "Because," the patient replied, "I'm the only person in the whole world who knows where I'm itching."

The medical profession alone knows what is best for the health needs of the public and what measures will sustain and provide adequate medical care on a quality basis consistent with scientific practices. While we know this to be true the public and legislators are not so minded, and as a result these lay groups and propagandists join with the politician in a nation-wide movement to create a new system for the providing of medical care and are ignorant of basic facts and conditions.

It is incumbent upon all of our members to educate these new deal proponents singly and collectively.

MEDICAL LEGISLATION

Elsewhere in this issue will be found the first "Legislature Flashes," transmitting information related to the bills that have been introduced in the present session of the legislature in so far as they relate to health and medical care. No attempt is made to dissect them or to indicate their apparent or hidden purposes. This will be done through other channels. These "Flashes" should indicate public and political trend. After all, the question of so-called state medicine, informed persons assert, will not be decided by the medical profession. The public will make the decision through its legislative representatives. Or rather, an organized minority of the public joining with an organized minority of politicians will write the ticket. That is the history of all new movements and new legislation.

The rôle played by medicine will be determined by how strong an organized group it can mobilize to shape, guide, and control the efforts and influence of the proponents for state-provided medical care. There rests the answer as to what medical legislation will be enacted during the next four or five months. Radical, ill advised, undesirable legislation to provide medical care under state or federal control can be defeated only by organizational influence and will depend upon the personal interest and work of every member. Therefore members should evidence constant interest in their county societies and unite in its representations.

LEGISLATURE FLASHES

On going to press (January 20) the "bill hoppers" of the legislature are crammed, the printing bureau is swamped, and the end is not discernible. The legislature adjourns January 22 for the customary thirty-day interval. More bills may then be introduced by general consent.

It has been impossible to obtain copies of bills relating to health and medical care because the printing department of the legislature is unable to keep up with the introduction barrage. Advance information gives the following as some of the bills that have been introduced:

Narcotic regulations.

Ten skeleton bills amending the Medical Practice Act.

X-ray Laboratory Bill.

*All articles listed under this caption, "This Month's Topics," have been written and sent to the Editor by the Association Secretary, Dr. Frederick C. Warnshuis.

Farm Bureau County Hospital Bill.
 Medical Service and Hospital Bill (Senator Williams).
 Venereal disease control.
 Hospital Insurance Bill.
 Medical Care Insurance Bill.
 Dental Bill.

All these comprise legislation that directly affect medical care and practice. Our Committee on Public Policy and Legislation is intensely engaged in its work, and is giving most thoughtful attention to legislative matters.

It is well to remind members and county societies that no action for or against any legislative enactments should be registered until our committee or the Council outlines attitude and position. In due time and course a digest will be sent to every county society with instructions as to action. Await those instructions, but be prepared to respond when word reaches you through your county officers.

THIS IS THE LAW!

Eighteenth—The certificate issued herein for the practice of midwifery may be revoked for the failure to have the following equipment (in each case): Nail brush; wooden or bone nail cleaner; jar of green or soft castile soap; rubber gloves; tube of sterile vaseline; clinical thermometer; agate or glass douche reservoir; two rounded vaginal douche nozzles; two rectal nozzles, large and small; one soft rubber catheter; blunt scissors for cutting cord; either lysol, carbolic acid, or bichloride of mercury tablets; boric acid powder; one per cent solution of nitrate of silver; medicine dropper; narrow tape or soft twine for tying cord; absorbent cotton (preferably in one-quarter pound packages); no other instruments are to be used by a midwife. [Amended 1915, p. 184; amended 1917, p. 93; amended 1921, p. 1009; amended 1925, p. 281; amended 1927, p. 99; amended 1929, p. 626.]

Queries: Why agate or glass reservoirs? Why rounded tips? How does the fluid in the reservoir pass to the tips? As some member said: "A resident interne or nurse would be tossed out on their ear if they attempted to douche a woman in labor or after labor has terminated." Who had an overstock of quarter-pound packages of cotton?

Yes, this is the law of today! Surely, its framers of yesteryears (1927 and 1929) were meticulous in drafting an inventory for the midwives' obstetrical bag.

ENDOWMENTS

A doctor of another state, in providing for a \$50,000 endowment fund contribution to his state medical association, wrote:

"What I am endeavoring to do is to create an unending service to the medical profession and through them a better service to the sick. A man who serves only while he lives, serves only for a very short period. I would like for my services—existing in some form—to go on indefinitely after my physical being has ceased to exist."

What a noble thought and deed! We trust that those of our members who are able will emulate that ideal and purpose, and provide that their services may go on indefinitely in our Association.

A SOUTHERN TREK

At 5 p. m. on Tuesday, January 6, President Pallette and your Secretary set forth in an unusual rainstorm from Los Angeles for Santa Ana, where Councilor Emmons was met, to attend the regular meeting of the Orange County Medical Society. At 8 p. m., in spite of the rain, some one hundred members of the county society convened. Addresses were made by the State Association officers, and until 10:45 p. m. a general discussion, with questions and answers, dealt with national, state, and local problems that were related to medical care, practice, public health, and social-economic problems vital to our members.

Orange County members constitute one of our most active county units. They reflect in a most satisfactory way that which can be accomplished by unity of purpose and action. They are meeting in a most admirable way all of the medical and public-health questions that concern their community and are rendering a service that inspires public confidence.

By 12:30 a. m. we were in Los Angeles, and though the rain continued, its discomforts did not dampen the enthusiasm engendered by this county meeting.

On Wednesday your president and secretary went to Riverside, where they were met by Speaker Roblee and Councilor Emmons. At 8 p. m., 108 members of the Riverside and San Bernardino County Societies and ladies sat down to dinner in the Mission Inn. The postprandial program was opened by two vocal and harp selections by local artists, and fixed the harmonious theme of the subsequent addresses and discussions presided over by Speaker Roblee.

The members of these two constituent units also reflected the cohesive unity of our Association, and impressed the State officials with the fact that they are loyal to all of our ideals and policies.

At 9 a. m. on Thursday, January 7, President Pallette, Speaker Roblee, Councilor Emmons, and the State Secretary set forth for El Centro, in Imperial County. We skip the snow on orange trees and blossoming roses in Redlands and the hunger urges of the back-seat riders. These cries and pleas were silenced in the lunch room of the Barbara Worth Hotel in El Centro at 2 p. m. Following this a run was made into Mexicali, where in Mexican environment we meditated upon the very apparent difference in the living conditions and customs of the natives. The Speaker terminated the visit by speeding us back to El Centro to the tunes of guitar-strumming street urchins.

At 7 p. m. thirty-four members of the Imperial County Society convened for their monthly meeting. A fine group of men and a 100 per cent society, having all eligible physicians as members. Their treasury has a sufficient balance to pay the 1937 State dues, so no assessment is being made on the members for this year.

On Friday morning, through icy roads, and snow, strange as that does seem, we began our return trip, leaving Doctors Roblee and Emmons at Riverside, and President Pallette was left in Los Angeles in time for late afternoon office hours. Your Secretary continued on to Santa Barbara.

On Saturday, January 9, the Scientific Program Committee and the officers of all scientific sections met for the purpose of reviewing and approving the program for the Del Monte meeting. Suffice it to state at this time that the 1937 scientific program will be most attractive and will impel a large attendance. Detailed announcements will appear in subsequent issues. Sunday, January 10, return drive was made to San Francisco.

Would that every member could visit all of our county units. He would become deeply impressed with these fellow members. He would gain a pride and feel an increased appreciation for his organizational affiliation.

COUNCIL MINUTES

Minutes of the Two Hundred and Forty-Ninth Meeting of the Council of the California Medical Association

Pursuant to the call of the Chairman, the Council of the California Medical Association convened in special session in the Sir Francis Drake Hotel, San Francisco, on Saturday, January 16, 1937, at 9:30 a. m.

1. **Roll Call.**—The meeting was called to order by the Chairman, with the following members present:

President Edward M. Pallette, Speaker William W. Roblee, Chairman Morton R. Gibbons, Councilors Karl L. Schaupp, Calvert L. Emmons, Carl R. Howson, Henry J. Ullmann, Axel E. Anderson, Alfred L. Phillips, C. E. Schoff, Henry S. Rogers, William H. Kiger, J. B. Harris, C. O. Tammer, T. Henshaw Kelly; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis, General Counsel Hartley F. Peart and his associate, Howard Hassard. Mr. Lionel Browne was present during the discussion of the report of the Committee of Five. Honorable Walter McGovern and Honorable Melvin I. Cronin addressed the Council.

Absent: President-Elect Morrow (on account of illness) and Councilors Hamlin and Wilson.

2. **Scientific Committee Report.**—A report of the meeting of the Committee on Scientific Work, held on January 9 at Santa Barbara, was given by the Secretary.

It was moved by President Pallette, seconded by Councilor Rogers, that, in accordance with the recommendation of the Committee on Scientific Work, the third general meeting be devoted to a discussion of health and hospital insurance. Carried.

3. Papers for Publication in Journal.—After discussion of the advisability of publication of a paper submitted for publication in the JOURNAL, it was moved by President Pallette, seconded by Councilor Rogers, that the paper as presented be published. Carried.

After consideration of the paper "Practice of Medical Problems in Hospitals," the Council agreed that there would be no objection to its publication in the JOURNAL under the names of the authors.

4. Exchanges.—Members in the southern part of the State, in an endeavor to build up the Reference Library of the Los Angeles County Medical Association, requested the Council to give consideration to obtaining two exchange copies of medical journals.

It was moved by Editor Kress, seconded by Speaker Roblee, that editors of state medical journals be requested to grant duplicate copies of their journal in exchange for two copies of CALIFORNIA AND WESTERN MEDICINE, one copy of the exchange journals to be sent to the San Francisco County Medical Society Library and one copy to be sent to the Los Angeles County Medical Association Library. Carried.

5. California Medical Economic Survey.—Deputy Attorney-General Lionel H. Browne, representing the State Board of Health, cosponsors of the California Medical Economic Survey, gave a résumé of the terms and conditions under which the survey had been conducted and the responsibilities of the State Board of Health and the California Medical Association. Deputy Attorney-General Browne read the resolutions relating to the survey adopted by the Board of Health at a special meeting thereof.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Rogers, that the Council of the California Medical Association approve the resolutions adopted by the State Board of Health. Carried.

6. Legislation.—Junius B. Harris, Chairman of the Committee on Public Policy and Legislation, gave a résumé of the present legislative activities and informed the Council of the committees appointed by the Senate and Assembly having to do with public health and medical practice.

The Secretary presented correspondence from Doctor Russel V. Lee of Palo Alto, together with proposed law for the control of venereal diseases. After full discussion, on motion of Editor Kress, seconded by Councilor Kiger, the following resolution was adopted:

WHEREAS, The federal, state, and local public health agencies have authorized and are putting into operation carefully prepared plans for a campaign for the prevention and treatment of syphilis and gonorrhea; and

WHEREAS, The utilization of federal funds in this work necessitates centralization of state procedures in and through the California State Board of Health; now therefore be it

Resolved, By the Council of the California Medical Association that it is in full sympathy with all rational and practical efforts to solve the problem of syphilis and gonorrhea; and be it further

Resolved, That this Council suggests that all groups and citizens who wish to cooperate in the work, do so in conjunction with the State Board of Health.

It was moved by Councilor Kelly, seconded by Councilor Ullmann, that the Council commend the San Francisco *Daily News* for its attitude toward the present campaign and publication of articles dealing with venereal diseases. Carried.

It was the consensus of opinion that the Code Commission's revision of the medical practice laws should be handled by the Secretary of the Board of Medical Examiners.

7. Legal Counsel.—The General Counsel reported on the complaint filed by a taxpayer in Kern County against the Board of Supervisors regarding the building of a branch hospital at Delano; and contempt proceedings about to be filed against the Supervisors for violation of the injunction in the case of *Goodall vs. Brite*. Mr. Peart

also reported on proposed amendments to the county hospital bill, definition of indigency, amendments on county hospital legislation.

8. Public Health and Welfare.—The Secretary presented correspondence from the American Medical Association and resolution from the Illinois State Medical Society regarding the United States Public Health Service. No action was taken pending the establishment of policies by the American Medical Association, and the entire matter was referred to the Executive Committee.

President Pallette called to the attention of the Council two statements which will appear in the January 16 issue of the *Journal of the American Medical Association* regarding health welfare and cooperation with State and local agencies. The formulation of a policy was referred to the Executive Committee.

9. Hospital Insurance.—Discussion was had of the extension of the Intercoast Hospitalization Association and the rider attached to the policy of that Association.

It was moved by President Pallette, seconded by Speaker Roblee, that the entire matter of the Intercoast Hospitalization Association be referred to the next meeting of the Council and that in the meantime the Secretary and the Chairman of the Executive Committee contact the president and other officers of the Intercoast Hospitalization Insurance Association and secure definite information. Carried.

10. Retired Memberships.—In accordance with provisions of the by-laws, the Secretary presented retired membership data signed by the respective county medical societies.

It was moved by Councilor Schaupp, seconded by Councilor Ullmann, that Charles D. Ball, M. D., member of the Orange County Medical Society, be granted retired membership in the California Medical Association. Carried.

It was moved by President Pallette, seconded by Speaker Roblee, that Charles G. Levison, M. D., member of the San Francisco County Medical Society, be granted retired membership in the California Medical Association. Carried.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Schaupp, that Cullen F. Welty, M. D., member of the San Francisco County Medical Society, be granted retired membership in the California Medical Association. Carried.

11. Noon Recess.—At this point a recess was taken for luncheon with the Legislative Committee of the two State Dental Associations.

12. Call to Order.—The meeting was called to order after the noon recess, with the following members present: Doctors Pallette, Roblee, Gibbons, Schaupp, Emmons, Howson, Ullmann, Anderson, Phillips, Schoff, Rogers, Kiger, Harris, Tanner, Kelly, Dukes, Kress, Warnshuis, and Mr. Peart and Mr. Hassard.

13. Hospital and/or Medical Insurance.—T. Henshaw Kelly, Chairman of the Committee on Hospital and/or Medical Insurance, presented the proposed act covering medical service association for discussion by the Council. The bill was considered section by section and certain amendments made.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Rogers, that the bill as amended be approved and that the Legislative Committee proceed to have it introduced forthwith.

A roll call vote was then taken and the motion was unanimously adopted.

Doctor Harris called the attention of the Council to the medical service bill introduced at the present session of the Legislature by Senator Dan Williams. It was the sense of the Council that this bill should be discussed at the Annual Conference of County Secretaries.

William H. Kiger, member of the Special Committee on Hospital Service Insurance, outlined the activities of the hospitals in the southern part of California and asked Doctor Kress to read the bill to govern hospital insurance as proposed by the southern hospitals.

The bill was read and discussed, and on motion of Councilor Schaupp, seconded by Councilor Phillips, the bill on hospital insurance as presented was approved, and Doctor Kiger was authorized to arrange for its introduction at his discretion. Carried.

14. **X-Ray Legislation.**—The x-ray bill as presented by the Pacific Roentgen Club was referred to the Legislative Committee for report at the February 7 meeting of the Council. Carried.

15. **Adjournment.**—There being no further business to come before the Council, adjournment was taken at 5:50 p. m.

MORTON R. GIBBONS, *Chairman*.
F. C. WARNSHUIS, *Secretary*.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

California Code Commission: Recodification of the Medical Practice Laws

A former legislature created a Code Commission for the purpose of rewriting and codifying existent laws.

When one reads some of the laws as they were drafted and passed, wonderment grows as to verbiage, verbosity, and interpretation. Why confusion results is easy to explain. Why attorneys, and even courts, arrive at differing conclusions is not hard to understand. But what else could be expected in view of the process that governs legislation procedure. To correct these errors, to clarify meaning and to correct errors in grammar, this Code Commission was created.

The Code Commission has been engaged in its task for several months. It has been very considerate in inviting interested groups to review its redrafts. After it had rewritten the medical practice law the Commission invited our Association to confer with a representative of the Commission and give advice and express opinion in order that the original intent and meaning of each section might not be altered.

The Council appointed a special committee, as did also the Board of Medical Examiners. These two committees and a representative of the Commission met and spent some twenty hours in checking every line and word of the redraft with the original law and completed the revision of this law. It is believed that it is now in a form that will be readily understood and interpreted. There was no authority to make any changes in basic provisions or intent or to include any amendments. Clarification was the sole objective. Verbosity was eliminated and grammatical construction was improved.

The Legislature will now approve this redraft, thereby placing in our statute code a well-constructed law. The following members rendered this service: Doctors J. B. Harris, M. R. Gibbons, Sr., Howard Morrow, T. Henshaw Kelly, State Secretary, Mr. Hartley Peart and his associate, Howard Hassard, for the Association, and Doctors C. E. Schoff, C. L. Abbott, C. B. Pinkham, and Mr. Lionel Browne for the Board of Medical Examiners.

Automobile Versus Airplane Deaths

An airliner with twelve passengers crashed and twelve deaths result. Extra newspapers, radio bulletins, three investigations, and congressmen gaining publicity through promises of introducing bills to create other investigations and useless laws. Papers blazing with many point-size headlines dealing with this unfortunate "crash," in a sixth or seventh page column item in small type report 1,061 deaths on the streets in one city caused by automobiles. Yet no comment follows on this slaughter on streets and highways.

Airplane travel is safe. It is safe from a mechanical standpoint because these plane accidents do not result from mechanical or plane failure. Plane travel is safe from the physical fitness of pilots' standpoint because

competent medical advisers and examiners have formulated physical standards for pilots. Airplane travel has a danger factor from an operating standpoint because operating officials are neglecting two important factors—judgment failure and weather conditions.

Judgment failure or man failure looms up when dispatchers and pilots ignore the elements, think they can ride through and delay in making emergency landings, or issuing grounding orders. Judgment man failure also occurs when the pilot runs into a blind spot, loses his course and bearings and continues to fly on at an altitude that is lower than the highest ranges on his course. Pilots should be drilled and drilled so that they know the peak altitudes of their terrain and be schooled and schooled that in emergencies or when encountering visibility that is nil that they shall immediately commence climbing to an altitude at least 1,500 feet higher than the highest peak on their course or terrain and maintain that altitude until they regain their bearing and necessary visibility. Observance of this rule will prevent crashes into sides of mountains. Storms and adverse flying conditions are reported on every course. The alert pilot should have courage to turn back or ground rather than to take a chance on riding through. If he does not, the operating dispatcher ought to exercise his authority and either issue orders to turn back or ground the plane in a safe emergency landing field. We have commended one pilot for taking us back and another for making an emergency landing even though we were grounded for four hours. Airplane travel is safe and will be safer when operating officials observe these two emergency rules.

As to the slaughter by automobiles, that will continue until legislators ignore the political pressure and influence of manufacturers and dealers and enact new laws governing automobile driving. What is needed is a law fixing standards of physical fitness that must be met to obtain a driver's license. A paper reporting a plane accident had an item imparting that an automobile driver was receiving a blind man's pension each month. Think of it!—vision so poor as to qualify for a blind person's pension, yet given a license and permitted to drive an automobile!

Another law or amendment is required to give police and patrol officers authority to revoke drivers' licenses of all who violate traffic laws. Leniency has generated disdain for traffic laws and encouraged violations.

Some day public opinion may overcome the mercenary policies of automobile manufacturers and dealers and bring about legislation and enforcement.

✓ ✓ ✓

SAFER IN AIR THAN ON HIGHWAYS

When one considers that the Sunday night accident to a United Air Lines plane, near Saugus, was the first serious crash in eleven years of the company's operations between San Francisco and Los Angeles, the tragedy is softened somewhat; and the growth of the flying habit among Americans is explained. Over the Coast route, this line has made 20,000 flights, totaling 7,000,000 miles, without a mishap to passengers, in multimotored planes, until this exception occurred.

On the same day, twelve lives were lost in highway traffic in Los Angeles County, with a total of more than one thousand victims for the year.

Thorough investigation was made of the air disaster, and every known remedy will be applied to prevent repetition. If the same degree of preparation and care should be directed to the prevention of motor-car accidents, better progress would be made toward safety on streets and roads.

Perhaps, after all, the greatest factor in continuing the terrific traffic toll is public apathy due to the average individual's smug belief that motoring may be dangerous for other persons, but not for him.—*Long Beach Press-Telegram*.

San Mateo County Society Sets an Example

The following communication reflects a commendable example for all of our county societies. Such contacts with boards of supervisors is bound to be productive of good, better understanding, and mutual satisfaction. Every county medical society should make similar contacts with their supervisors and legislators. We congratulate and

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

commend the members of San Mateo County in this well-directed activity. They are discharging a county society function that is quite important.

1 1 1

SAN MATEO COUNTY MEDICAL SOCIETY

December 31, 1936.

To the Honorable Board of Supervisors of San Mateo County, Redwood City, California.

Gentlemen:

Since the recent election there has been a feeling on the part of the members of the San Mateo County Medical Society that our organization should communicate with you gentlemen to transmit our ideas in regard to the County Department of Health and Welfare. Informal discussion with some of your board confirmed our feeling that you might like to hear from us and have our Society form a standing committee which would be ready at any time to cooperate with your board.

It is our opinion that you gentlemen, constituting as you do the first Board of Supervisors elected at large according to the provisions of the county charter, are going to stand for improved governmental conditions in our county. As citizens of the county we, too, want good government, and as physicians who helped to formulate the health and welfare provisions of the charter, we feel vitally interested in these provisions.

As a body of medical men and women who are in almost constant intimate contact with public health and welfare matters, we respectfully submit the following suggestions which we hope will prove of value when the health and welfare provisions of the charter are under consideration by your board. We should like to have it understood at the outset that it is not our desire to criticize anything that has been done in the past. We offer these suggestions exactly as they might have been offered when the charter first went into effect.

The administrative head of the county government is a highly important official whose appointment is entirely in the hands of your board. Under his jurisdiction the county executive has, among other departments, the Department of Health and Welfare, and its efficient operation is dependent upon his administrative ability. The charter calls for the appointment by the executive of an advisory board of health and welfare, whose duties primarily are to aid the executive in selecting a director of public health and welfare, to advise with the executive, the director, and the various department heads in this division. The functions of this board are of great importance, and a good executive will select such a board with careful consideration and, having selected it, will make frequent use of it and discuss freely with its members the policies and operations of the department.

We feel that the position of director of public health and welfare should be filled by a physician who is sufficiently mature in years to have gained experience in dealing with people, that he should have executive ability, that he should be a man who meets with the approval of the physicians of the county, and that he should have some special training and experience in this type of work. The modern trend in medicine is to attempt to have every physician consider himself a volunteer health officer, and to have him working hand in hand with the Public Health Department. It follows that no public health director can efficiently run his department without close cooperation on the part of the physicians in his community.

An important position under the Department of Health and Welfare is that of superintendent of the county hospital. Again it is necessary to have a man who enjoys the confidence of the medical profession. Most of the medical and surgical service at the hospital is rendered gratis by the doctors of the community, which, we feel, results in standards of service higher than they would be if physicians were employed to do the work. Furthermore, this service, if paid for by the county, even at minimum rates, would be a tremendous burden to the taxpayer. Further requisites of the hospital superintendent are that he should be a competent medical man and should possess executive ability. He should run the hospital as economically as possible in keeping with good hospital care.

The Department of Social Service is responsible for the admission of patients to charity service in the hospital and clinics, and for the care of the poor, the blind, etc., in the home. It is not an uncommon practice on the part of certain people to attempt to get free hospital and medical care at the expense of the county even though they could, by no stretch of the imagination, be called indigent. This is an unfair burden on the respectable citizen, who pays taxes to maintain these institutions and who at the same time must provide for his own care and for that of

his family in case of accident or illness. It is also unfair to the doctors who contribute their time and skill in an effort to provide proper care for those who are supposed to be indigent. It is probable that every county in the State of California has at some time, in the course of its history, had county officials who made a practice of repaying political favors by influencing the Social Service Department in such manner that the department would make possible the admission of non-indigents to the county hospital. Obviously, the taxpayer and the doctor pay the bill. Another practice, unfortunately only too common, has been the appointment of political favorites to the positions of investigators in the department. It is the feeling of the County Medical Society that such policies are not consistent with good county government.

The superintendent of social service should be a person who has had wide training and experience in the work. He or she should possess real business ability, and at the same time have enough humanitarianism to treat decently those who are really in need. The superintendent should be free of all political pressure, should be able to appoint his own workers, and should be directly answerable to the director of health for his results.

Referring again to the Department of Public Health, we would like to suggest that a concerted effort be made to bring all of the people of the county under this department by inducing the cities to abolish their local departments and to contract their health work to the county. The county department serves only a relatively small fraction of the population, a condition not consistent with economical administration. If the various city officials have confidence in the County Department of Public Health, they should be glad to eliminate their local departments. We feel that you gentlemen have a unique opportunity to restore confidence in the government of our county and so make possible for unification of public health work under one head, the Director of Public Health and Welfare.

In summary, we feel that we have at present a Board of Supervisors, composed of men of sound business sense. In the administration of county government it is our opinion that where competent executives are placed at the head of the several departments, it is unnecessary for the Board of Supervisors to feel called upon to dictate the policies of, and make appointments in, these departments, maintaining, of course, its power of veto. It would seem that unnecessary confusion would be eliminated and adverse publicity avoided if the board felt sufficient confidence in its department heads to refer the complaints of constituents to the department involved. We feel sure that you gentlemen will agree with us when we say that political patronage is not consistent with good county government.

In this communication our motive has been to lend helpful suggestions. As physicians and fellow taxpayers we are interested, on the one hand, in the efficient operation of our County Health Department and all of its branches, and on the other hand, in the economically sound administration of county government. It is with the hope that we may cooperate with the Board of Supervisors toward these ends that this communication is respectfully submitted.

Very truly yours,

THE SAN MATEO COUNTY MEDICAL SOCIETY.

Objectives of the California Heart Association

The aim of the California Heart Association shall be the better education of both the medical profession and the general public in heart disease and its resultant disability:

Medical Activities

1. Arrange for diagnostic clinics and postgraduate education work in rural areas.
2. Seek representation of cardiac problems on programs of local county medical association meetings.
3. Sponsor two major yearly symposia on heart disease, one in San Francisco and one in Los Angeles.
4. Provide some method by which physicians may obtain postgraduate consultation on individual problems within the limitations of the standards of the American Medical Association and where direct consultation service is not available.
5. Foster a wide membership in state and national heart associations.
6. To accumulate and have available for all physicians in the State the latest proved methods for the handling of cardiac disease.
7. To promote uniform criteria for diagnosis and records among the general profession.
8. To study the etiology of cardiac and circulatory disease by accumulation of data and to act as an authorita-

tive source in dispensing proved scientific knowledge in this field.

9. To foster and guide worth while research in the field of cardiovascular disease.

Public Relation Activities

1. To coöperate with public health departments, school health departments, social and health agencies, and other organized groups in all constructive efforts to present information tending to aid in the cure and prevention of heart disease.

2. To coöperate with industrial and insurance companies relative to the employment, hazards, and liability of persons with circulatory defects.

3. To prepare educational exhibits for presentation to the public.

4. To present approved heart educational material to the general public by means of newspaper releases, radio programs, moving-picture films, news letters, and pamphlets.

General Activities

1. To combat misinformation about heart disease and make every attempt to combat quackery.

2. To consider the provisions made for convalescent cases, not ill enough to require hospital care, but not well enough to work and to foster a rehabilitation program.

3. To attempt to arrange a proper evaluation of the status of the heart in industry and employment.

4. To attempt to arrange the proper evaluation of the insurability of heart disease.

5. To properly evaluate the natural resources of California as applied to the treatment, the care, and the residence of those people afflicted with heart disease, and those other people from other localities who select this state as their place of residence.

6. To investigate and promote all proved methods for the institution of preventive measures in heart and circulatory disease.

Federal Resettlement Administration

This federal agency was formed to grant aid to farmers in drought-stricken areas. The Administration purposes to aid agriculturists to rehabilitate their farms or gain a new location for their agricultural labors. Clients of this Administration are the recipients of loans from the Government.

In the course of its activities this Resettlement Administration has prepared articles of incorporation and by-laws under which, by coöperative methods, the clients can organize for the purpose of providing medical care for themselves and their dependents. Such a corporation has been formed in North Dakota. Now the information at hand indicates that the forming of a similar corporation is contemplated by Mrs. R. B. Maycock, Chief of Home Management Section, and Mr. D. G. Hildebrand, Supervisor of Los Angeles County, and that they have "set out to find some hospital group or clinic that will undertake to provide medical service for clients of the Administration in Los Angeles County.

The articles of incorporation provide, among other things:

To associate its members together for their mutual benefit and to further the rehabilitation of said members and to that end to engage in any activity involving or relating to the obtaining for its members of medical and dental treatment and services and any surgery, nursing or hospitalization, necessary or convenient thereto.

... and to make provision for the payment of and pay bills rendered to its members by physicians and dentists. . . .

In North Dakota, physicians are asked to render these services for a fixed fee, and physicians unwilling to coöperate are being listed as "ineligible"—black-listed.

Here, then, is found another plan of bargaining for medical care for federal clients under terms and conditions prescribed by the lay group. At present no approach has been made to accredited representatives of our profession. Probably the "ticket" will be written and then the members of the profession will be asked to underwrite it. How long will it be ere federal and state representatives will learn the wisdom of first consulting with medical representatives before they formulate their plans and procedures for providing medical care?

COMPONENT COUNTY MEDICAL SOCIETIES

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was called to order by the president, Dr. Frank MacDonald, on November 17, 1936, at the Auditorium on Twenty-ninth and L streets. Some seventy-two members and guests were present.

The paper of the evening was given by Dr. W. W. Cross of Oakland, on *A Review of Four Hundred and Seventy Cases of Pyelonephritis*. The speaker stated this disease may occur from the ages of three to seventy-six, and is three times more common in females than males. The commonest organism found, in the order of their frequency, are colon bacilli, staphylococcus, and streptococcus. Pyelonephritis usually occurs in the course of a general infection, so the primary focus must be sought elsewhere. The bacteria may be carried to the kidneys in three ways—by the blood stream, through the lymphatics, or ascending from mucous membranes lower down the tract. Ptosis, strictures, and obstructions of other types may serve as exciting causes through interference with proper urinary drainage. Microphotographs, beautiful because of the manner in which the stains brought out the details, were shown, comparing normal and pathologic structures.

The paper was discussed by Doctors Hale and Beach, who, together with Doctor Isoard, thanked the speaker for his splendid presentation of the subject.

The report of the Board of Directors was read. Doctor MacDonald stated lodge practice violated at least five of the Principles of Medical Ethics as applied to contract practice, and presented the following resolution from the Board of Directors for action by the Society:

WHEREAS, Certain lodges, orders, and fraternal organizations provide medical services as an inducement to membership in these organizations and

WHEREAS, In the opinion of the Board of Directors of the Sacramento Society for Medical Improvement, the sale of such medical services through contracts with private physicians constitutes the practice of medicine; therefore be it

Resolved, That such practice of medicine by lodges, orders, and fraternal organizations be disapproved by the Board of Directors of the Sacramento Society for Medical Improvement; and be it further

Resolved, That the above resolution shall become effective only if it is endorsed by the majority of individual members at the next regular meeting of the Sacramento Society for Medical Improvement.

Doctor Reardan moved that the resolution be laid on the table. Seconded by Doctor Vance.

Discussion:

Doctor Teall asked, "Is this an ethical question or one of political politics? Will the Code of Ethics apply equally to violations by old-established men as well as by newer members of the Society?" He asked for a definite policy to guide the younger men.

Doctor Dozier asked for instructions as to how the Board of Directors should act in prosecuting violations of the Code of Medical Ethics.

Doctor Hale: This is an old and moot question which has been inherited from the past. This type of practice is unethical, but since we are divided on it, it should be laid on the table. If someone resigns, before night another doctor may seek the appointment or else an osteopath with an M. D. degree will take it or else new doctors may come in and take it. I recommend a gradual process to prevent new evils and in time to correct the old even as in correcting the county hospital situation here.

Doctor Lawson: I ask for consistency. We have disapproved the Mutual Benefit Health and Accident Association and approved the Intercoast Hospitalization Insurance Association. There is no justice in acting definitely regarding certain orders and tabling action against others in the same category.

Doctor Isoard: On account of agitation for State medicine, let the problem of lodge practice be undisturbed.

Doctor Reardan: A new member, in the past, once tried to gain admission to the Society, so he resigned his lodge connections and immediately a member of the Society took over the work.

Doctor Schoff: The Board of Directors have been zealous in enforcing the Code of Medical Ethics, for which they should be complimented. Harmony should prevail now because the action of the Sacramento Society for Medical Improvement, at the last meeting of the State Legislature, was chiefly responsible for defeating Senate Bill No. 454.

Upon putting the motion to a vote to table the matter, it carried—42 to 14.

The report of the delegates to the State meeting, by Doctor Hale, stated the delegation showed a definite trend to the right in dealing with economic problems and by their voting. State dues were fixed at \$15 by the House of Delegates.

* * *

The annual business meeting of the Sacramento Society for Medical Improvement was called to order by the president, Dr. Frank MacDonald, on December 15, 1936, at the Auditorium on Twenty-ninth and L streets. Thirty-seven members were present.

The financial and membership report of the secretary was read. A motion was made, and seconded, that the dues be \$20 for 1937. The motion was lost. A motion was made, and seconded, that dues be \$15; also was lost. A motion was made, and seconded, that the dues for 1937 be \$17.50. The motion was passed.

The following were elected as members on the Board of Directors for 1937: Wallerius, Schluter, Van Den Berg, Cook, Dozier, Ankele, Kanner, Christman, and Fanning.

Doctor MacDonald was unanimously elected to serve as delegate with Doctors Hale and Scatena for 1937. Doctor Pollock was elected to serve as alternate with Doctors Cook and Christman for 1937.

Dr. Glenn E. Millar was nominated and elected secretary-treasurer of the Sacramento Society for Medical Improvement.

NORRIS R. JONES, *Secretary*.

*

PLACER-NEVADA-EL DORADO-SIERRA COUNTIES

The Placer County Medical Society met at the Freeman Hotel Saturday evening, January 9. The meeting was called to order by President C. E. Lewis at 8:15 o'clock. In addition to President Lewis, there were present the following members and visitors:

Members—Doctors E. E. Lundegaard, L. B. Barnes, Daniel L. Hirsch, Robert A. Peers, Ray C. Atkinson, Mildred E. Thoren, Max Dunievitz, W. A. Vinks, D. M. Kindopp, and C. C. Briner.

Visitors—Mr. W. F. Higby of San Francisco, executive secretary of the California Tuberculosis Association, and Miss Lu Crandall of Auburn, Public Health nurse.

This being a meeting devoted to the subject of tuberculosis control, the secretary, at the request of President Lewis, gave a short address on the essentials in the control of tuberculosis and discussed the proposed plan of the Placer County Tuberculosis Association's campaign for tuberculin-testing school children of Placer County.

The secretary introduced Mr. W. F. Higby, who gave a history of the antituberculosis movement in California since 1904 to date, outlining the various steps taken by the California Tuberculosis Association between these dates. Mr. Higby stated that it is the policy of the California Tuberculosis Association to work in cooperation with the various county medical societies. He outlined the tuberculin-testing programs which are being carried on in forty counties in California, always in cooperation with Organized Medicine.

Following Mr. Higby's address, a resolution of endorsement of the tuberculin-testing program of the Placer County Tuberculosis Association was adopted.

Doctors Atkinson and Briner exhibited a moving-picture film relating to childhood tuberculosis and tuberculin-testing.

The meeting then adjourned for refreshments.

ROBERT A. PEERS, *Secretary*.

*

SAN BERNARDINO COUNTY

The meeting of the San Bernardino County Medical Society was held at the San Bernardino County Charity Hospital on Tuesday, December 1, 1936.

The meeting was called to order by the president at 8:15 p. m. About sixty members and guests were present.

A letter from Doctor Card was read and details regarding the joint meeting with the Riverside County Society on January 6 explained. The joint meeting for the officers of the California Medical Association will replace the regular meeting in January.

The program of the evening was given as a medical clinic by Dr. Phillip A. Corr of Riverside.

The following cases were presented and a short differential diagnosis given, preparatory to detailed discussion of treatment by Doctor Corr:

Diabetes Mellitus. Simple office management was stressed and protamine-insulin briefly discussed.

Pernicious Anemia. Various preparations used; cost and potency compared.

Pellagra. This case formed the basis of an excellent discussion of vitamins in general.

The cases were discussed by Dr. G. S. Landon of San Bernardino, Dr. Harold Gentry of Redlands, Dr. J. W. Neighbor of Arrowhead Springs, and was followed by a most enthusiastic and stimulating general discussion.

The meeting adjourned at 10:20 p. m., following which refreshments were served.

*

SAN MATEO COUNTY

The San Mateo County Medical Society met on December 23, 1936, in the banquet room of the Benjamin Franklin Hotel.

The guest speaker of the evening, Dr. Stanley Mentzer, presented a most illuminating discussion on the most recent advance in the diagnosis of gall-bladder disease, involving a new concept—obstructive cholecystitis. Doctor Mentzer's talk was illustrated with lantern slides, and was discussed by Dr. Carl Hoag and Dr. James Rinehart.

The secretary read a resolution pertaining to the attitude of the San Mateo County Medical Society concerning the corporate practice of medicine. A motion was made and seconded that the resolution be adopted in its entirety and was passed unanimously.

Dr. William Murphy read a letter that had been prepared by the Committee on County Affairs to be delivered to the Board of Supervisors of San Mateo County. Following the reading of the letter, a motion was made and seconded that the committee be empowered to submit the letter to the Board of Supervisors, with the approval of the San Mateo County Medical Society. This motion was passed unanimously.

Doctor Wade Macomber read a letter he had received from the United States Government concerning examination, vaccination, and typhoid inoculation of members of the Civilians' Military Training Camp, such medical service to be contributed by the physician. Dr. Frank Holmes Smith felt that the Civilians' Military Training Camp was a worthy cause, and agreed to take over the work for San Mateo County.

The chairman made an announcement concerning the nurses' fund for Mills Hospital and the San Mateo Community Hospital, following which a collection was taken. The collection amounted to \$40, and the secretary was directed to withdraw \$10 from the treasury as an additional contribution.

The secretary read a letter he had received from Dr. H. Henderson concerning her work in Daly City in regard to immunization and vaccination of school children. Following open discussion, the secretary was directed to write to Doctor Henderson, stating the facts in the case.

Dr. William Murphy, chairman of the Committee on Vaccination and Immunization of School Children, gave a report. The motion was seconded and carried to accept the report as read.

Dr. Carl Hoag, chairman of the Committee on Hospital Service Insurance, gave a report from his committee. The report was approved with recommendations concerning the policy of the San Mateo County Medical Society in connection with hospital service insurance in the coming year. Dr. Harold Hill made a motion that the committee continue to function and report to the Society as progress is made in the development of hospital insurance in the Bay counties. The motion was seconded, and carried.

A report was heard from Dr. William Knorp, chairman of the Public Health Committee. Doctor Knorp mentioned particularly the work that has been done and the program outlined by the San Mateo County Tuberculosis and Health Association. On motion, unanimously passed, the report was accepted.

The election of officers resulted as follows: Frank Gregory, president; Hartzell Ray, vice-president; J. Garwood Bridgman, secretary. Board of Directors—Olin M. Holmes, William Murphy, William Knorp, Erma Macomber, N. D. Morrison, Frank Gregory, and J. Garwood Bridgman. J. GARWOOD BRIDGMAN, *Secretary*.

✻

SANTA BARBARA COUNTY

The annual banquet meeting of the Santa Barbara County Medical Society was held at the El Paseo on Monday evening, January 11. Fifty-seven members and five guests were present.

At the conclusion of the dinner, Dr. P. A. Gray announced the results of the election of officers for the year: Irving Wills of Santa Barbara, president; Edward Lamb of Santa Barbara, president-elect; A. L. Mollath and Albert Missall, both of Santa Maria, vice-presidents-at-large; William H. Eaton of Santa Barbara, secretary-treasurer. Council—Hugh Freidell and H. E. Henderson, both of Santa Barbara, and O. C. Jones of Santa Maria.

Amendments to the Society's by-laws were given their last reading, and were unanimously adopted.

Amendments to the Society's constitution were given their second reading, and were ordered held for their final reading and adoption at the February meeting.

Retiring President Gray reviewed briefly the work of the Council for the past year, complimenting the members upon their accomplishments; and he also expressed his appreciation and thanks to the members of the various committees for their splendid coöperation and services. He then introduced Dr. Irving Wills, the newly elected president.

Following a few introductory remarks, President Wills introduced the speaker of the evening, Dr. Alice Solomon of Berlin, Germany. Doctor Solomon's life work has been social service, and she gave an extremely interesting and instructive talk upon the social service work in France, England, and Germany, commenting on comparisons, and stressing the importance of this work in the future development of the human race. At the conclusion of the talk she answered pertinent questions, which brought to an end a very enjoyable evening.

WILLIAM H. EATON, *Secretary*.

✻

TULARE COUNTY

The regular December meeting of the Tulare County Medical Society was held, by invitation, with the Tulare-Kings Dental Association. A dinner at Motley's Café preceded the joint meeting.

The guest speaker of the evening was Dr. Herman Becks of the University of California. He presented the subject of *Bone Pathology or Biology in Relation to Dental Medicine*, profusely illustrating the talk with lantern slides and also showing a set of typical x-ray reproductions that are being used as a basis for diagnostic comparisons. KARL F. WEISS, *Secretary*.

Leslie J. Seeley, from Siskiyou County to Shasta County.

In Memoriam

Green, Louis David. Died at San Francisco, January 14, 1937, age 55. Graduate of Denver and Gross Medical College, 1909, and licensed in California the same year. Doctor Green was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

✻

Moffitt, Thomas William. Died at Hollywood, January 4, 1937, age 67. Graduate of Starling Medical College, Columbus, Ohio, 1893. Licensed in California in 1923. Doctor Moffitt was a member of the Los Angeles County Medical Association, the California Medical Association, and the American Medical Association.

✻

O'Connor, Thomas Charles, Jr. Died at Lodi, January 13, 1937, age 44. Graduate of the University of California Medical School, San Francisco, 1927, and licensed in California the same year. Doctor O'Connor was a member of the San Joaquin County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

✻

Wagner, Henry Lewis. Died at San Francisco, December 27, 1936, age 77. Graduate of the Julius Maximilian Universität, Würzburg, Bavaria, 1884. Licensed in California in 1887. Doctor Wagner was a retired member of the San Francisco County Medical Society, the California Medical Association, and the American Medical Association.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

Component Auxiliaries

Los Angeles County

A Christmas program featured the luncheon of the Woman's Auxiliary to the Los Angeles County Medical Association on December 22 at the County Medical building. Only about fifty members were present, but it was one of the most delightful meetings of the year. The choir boys from St. Thomas' Episcopal Church gave a beautiful selection of Christmas music, and the table decorations were particularly festive and attractive.

It was announced that \$26 had been made at the recent party given by Mrs. Joe Zeiler in her own home, which sum will be used for circulating health plays among the schools.

Dr. Harlan Shoemaker announced plans for President Roosevelt's birthday ball, being sponsored by the County Medical Society, and asked the coöperation of the Auxiliary.

✻

Fresno County

On December 1 the Fresno Auxiliary to the California Medical Association held a card party in place of the regular meeting. The purpose of this party was to obtain funds to purchase subscriptions to *Hygeia*.

We are happy to report we were successful in obtaining fifty-five subscriptions. Thirty-five of these are pri-

†As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

vate and twenty are to be placed around in the community in such places as large beauty parlors, three high schools, the State College, County Library and its branches.

Fifty persons attended the party, which was a very enjoyable affair.

MRS. KENNETH J. STANIFORD.

San Diego County

The regular luncheon meeting of the Auxiliary to the San Diego County Medical Society was held December 8, 1936, at the University Club. The president, Mrs. F. G. Lindemulder, conducted the meeting.

It was announced that the Medical Society Bulletin has given one full page for our use. Mrs. R. Emerson Bond will be editor for this page.

Posters are to be given to every member of the Auxiliary for use in the doctors' offices. The posters will tell of the radio programs sponsored by the American Medical Association.

Mrs. E. H. Christopherson announced work of the public relations group. Mrs. Elmo Crabtree held a quiz on *Hygeia*, with a review of the value of the magazine.

Members of the Auxiliary presented a play, "A Doctor's Christmas," written by Mrs. Mark Glaser, State Chairman of Hygeia.

ELIZABETH R. BOLFORD.

San Francisco County

The monthly meeting of the round table on *Causes and Cure of War* was held on Wednesday, January 6, at the County Medical Society building, under the leadership of Mrs. Fred H. Zumwalt. Dr. E. Guy Talbot, western secretary of the National Council for Prevention of War, gave a very enlightening and stimulating talk on *Can We Keep Out of War?* He answered that question by first showing the ever-growing trend toward a European war, with the United States involved. Dictatorships, the scrapping of treaties, and the armament race, combined with the Spanish and Japanese situations, are bringing us nearer to a general conflagration.

Doctor Talbot stated that the causes of war are political, economic, and psychological, and that at the present time certain newspapers and magazines are building up an emotion of hatred, which was a great factor in the Spanish-American and World wars.

There are three important bills before Congress now that, if passed, would be a factor in the prevention of involving the United States in war. First, the bill to nationalize the munitions industry, that is, control by the Government. Second, to take the profits out of war, which is a bill presented by the Nye Investigation Committee. This committee found that for every three men killed in the World War, one millionaire was made. And third, a bill to strengthen the neutrality legislation. At present our neutrality bill expires in May, and it applies only to the embargo on implements of war. Doctor Talbot thought that it should also apply to raw materials, as oil, cotton, etc.

To close his talk, Doctor Talbot quoted a small line from Admiral Sims' article in *Freedom of the Seas*, which holds the kernel of the situation:

"... a decent regard of humanity should be placed ahead of gold."

MRS. EDWARD M. LIPSETT.

Santa Clara County

A luncheon was given by the Woman's Auxiliary to the Santa Clara County Medical Society on Monday, January 4, at the Hotel De Anza.

Dr. Dorothy Hazeltine Yates, assistant professor of psychology at San Jose State College, was guest speaker, her subject being *Psychology in Everyday Practice*.

Opposition to Forced Retirement Law for Physicians.—In a recent letter it was stated that a bill, termed the "Pomaret law," had been introduced in the French legislature according to which the members of all professions will be obliged to surrender their diplomas at the age of sixty-five and discontinue their work without any recompense in the form of a pension from the state. Violent opposition to such a proposal is appearing from all sides, and a medical journalist said that he would be eligible for retirement in three months and then either be ready for the soup line by 1939 or be obliged, like so many unemployed here in Paris, to earn a living by singing in the streets. Maurice Mordagne, the leader of the medical students' union, quotes such a letter received by him, in an article in the August 22 *Press médicale*, which reflects the reaction of the professors and medical journalists on the forced retirement bill. As to the faculties, Professor Villard of Montpellier is quoted as saying that the medical profession in France does not seem to have awakened to the potential dangers of such a bill if passed. Many physicians would be obliged either to die of hunger or seek asylum in a charitable institution. Another professor of the Paris Medical School who is familiar with conditions in smaller communities states that the applications of such a law would give temporary relief in an overcrowded profession only if some measures were adopted to reduce materially the numbers of licenses to practice granted annually. Professor Sergeant stated that every effort must be made to fight against the dangers of state medicine, which threatens to reestablish the serfdom suppressed by the French Revolution.

The proposed law would affect not only members of the technical (physicians, dentists, architects, engineers) but also those of non-technical professions (teachers in liberal arts); hence Professor Fedel of one of the high schools is quoted as saying that many discoveries have been made by men and women above the age of sixty-five. The campaign to retire such individuals without pension at that age is being led by ignorant opportunists and recently naturalized foreigners. Why not apply such a law to holders of public offices, many of whom have rendered the state invaluable service after the age of sixty-five? Many physicians even at seventy are still active and in possession of all their faculties, thus rendering indispensable aid by their advice, gained through many years of experience, to younger colleagues. Professor Faure, gynecologist, cited instance after instance of men of seventy or over who were a contradiction of the statement made by the supporters of the bill that a surgeon ought not to operate after the age of sixty-five.

The syndicat (union) of physicians in the department of the Seine has recently studied the records of one hundred foreign students and physicians during a period of four months and found that the majority of those who applied for naturalization and permission to practice were granted these demands by the government. It would appear more necessary to subject such applications to a stricter control than to try to force retirement of older men. The latter, if the bill passes the legislature, would not help young graduates born in France or its colonies as much as it would the recent influx of foreigners.—*J. A. M. A.*

Congress of Physical Therapy, X-Ray, and Radium.—The second cruise of the Latin-American Congress of Physical Therapy, X-Ray, and Radium will take place March 9 to 28, to Guatemala City, Guatemala. One boat will sail from Philadelphia March 9, and another from New Orleans March 10. The congress has been arranged for the week of the inauguration of the president of Guatemala, and visitors will participate in the festivities at that time. There will be three scientific sessions—Tuesday morning and afternoon, March 16, and Saturday morning, March 20—at the National University School of Medicine, the intervening time to be spent in a trip to the interior of Guatemala. Physicians who wish to attend should apply to Dr. Norman E. Titus, 730 Fifth Avenue, New York, president of the congress, or to Dr. Cassius Lopez de Victoria, 1013 Lexington Avenue, executive director.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11. Olin West, M. D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 3-6. F. C. Warnshuis, M. D., 450 Sutter Street, San Francisco, secretary.

1 1 1

Pacific Coast Surgical Association, Seattle, Washington, and Victoria, B. C., February 24-27. H. Glenn Bell, M. D., University of California Hospital, San Francisco, secretary.

Medical Broadcasts*

American Medical Association

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts, under the title "Your Health." The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title "Your Health," was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "Medical Emergencies and How They Are Met." The new series is built around the central idea that "one hundred thousand American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Blue network instead of the Red, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the health magazine, and three weeks in advance in each issue of the *Journal of the American Medical Association*.

The time of the broadcast is Tuesday afternoon, two o'clock, Pacific time.

1 1 1

San Francisco County Medical Society

A radio broadcast program for the San Francisco County Medical Society for the month of February is as follows:

Tuesday, February 2—KYA, 6 p. m.
Tuesday, February 9—KYA, 6 p. m.
Tuesday, February 16—KYA, 6 p. m.
Tuesday, February 23—KYA, 6 p. m.

1 1 1

Los Angeles County Medical Association

The radio broadcast program for the Los Angeles County Medical Association for the month of February is as follows:

Tuesday, February 2—KECA, 10:30 a. m., The Road to Health.
Saturday, February 6—KFI, 9:15 a. m., The Road to Health.
Saturday, February 6—KFAC, 10:15 a. m., Your Doctor and You.
Tuesday, February 9—KECA, 10:30 a. m., The Road to Health.
Saturday, February 13—KFI, 9:15 a. m., The Road to Health.
Saturday, February 13—KFAC, 10:15 a. m., Your Doctor and You.

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Tuesday, February 16—KECA, 10:30 a. m., The Road to Health.

Saturday, February 20—KFI, 9:15 a. m., The Road to Health.

Saturday, February 20—KFAC, 10:15 a. m., Your Doctor and You.

Tuesday, February 23—KECA, 10:30 a. m., The Road to Health.

Saturday, February 27—KFI, 9:15 a. m., The Road to Health.

Saturday, February 27—KFAC, 10:15 a. m., Your Doctor and You.

Wage Worker May Have Only One Federal Account Number.—Regardless of the number of employers a wage-worker may have, he can have only one account number or identification card for participation in the federal old-age benefits system under the Social Security Act, the Social Security Board emphasized today.

In issuing this statement, in response to inquiries from various sections of the country where workers having more than one employer have reported receipt of more than one identification card with differing account numbers, the Board advised each employee affected to take or send such cards to his local post office, where proper correction will be made.

The Board stated that this situation was due to the erroneous belief on the part of employees that they should file an application with respect to each job.

In emphasizing that an employee can have only one Social Security account number, the Board explained that the number of the account is permanent and is not affected by number of jobs engaged in or by changes in employment.

However, an employee who gives good reasons to the Social Security Board may have his account number changed.

The American Public Health Association's Sixty-Sixth Annual Meeting.—The American Public Health Association announces that its sixty-sixth annual meeting will be held in New York City, October 5-8, 1937.

A large eastern membership will receive that information with satisfaction. Not since 1921 has the Association met in the world's greatest city.

The sixty-fifth annual meeting took place in New Orleans in October. It attracted an attendance of 1,650 health authorities, representing forty-five states, Canada, Cuba, Mexico, and nine other foreign countries. The officers of the Association are reminding themselves of this registration in a state where the membership numbers less than one hundred and asking themselves what the registration will be in New York City, where the membership counts up to nearly five hundred within the city limits alone. An overnight's ride will enable more than one-half of the Association's five thousand members to attend the convention.

The National Organization for Public Health Nursing will meet with the American Public Health Association in 1937 for the first time. This large and important organization is expected to add another thousand to the registration lists.

The following related societies will meet with the Association as usual: The American Association of School Physicians; International Society of Medical Health Officers; Conference of State Sanitary Engineers; Conference of State Laboratory Directors; Association of Women in Public Health; and Delta Omega.

Dr. Reginald M. Atwater is the executive secretary of the Association, and the headquarters offices are at 50 West Fiftieth Street, New York, N. Y.

Social Security Allotments.—Federal grants totaling approximately \$2,326,000 for public assistance in three states were announced by the Social Security Board recently. California receives \$562,224.67 for aid to the needy blind and to dependent children; Connecticut, \$525,035.18 for aid to the needy aged; and Washington, \$1,238,731.06 for all three forms of assistance. California, as well as Washington, is among the twenty-four states cooperating in all of the public-assistance programs under the Social Security Act.

The amounts allotted to the states for each form of assistance and the number of individuals being aided under each plan, according to December estimates based on reports for the past nine months, are as follows:

State	Aid to	Federal Grant January 1 to March 31, 1937	Estimated Number of Individuals Aided in December
California	Blind	\$222,075.00	4,600
California	Children	340,149.67	22,650

With about 1,117,200 needy aged, 32,160 needy blind, and 290,240 dependent children receiving assistance from combined federal and state funds, it is estimated from reports for the past nine months that in December a total of approximately 1,439,600 persons were being aided under these three provisions of the Social Security Act. Forty-three states (including the District of Columbia and Hawaii) have plans approved under the Act for one or more of these programs—forty-two for old-age assistance, twenty-eight for aid to the needy blind, and twenty-seven for aid to dependent children.

University Enrollments in the United States: Fall Semester, 1936-1937.—The following figures have been compiled from the recent article in *School and Society* by President Raymond Walters of the University of Cincinnati. The original statistics did not separate the University of California at Los Angeles from the total figures for the University of California.

California (Berkeley alone, 13,681)	22,122
Columbia	14,662
Minnesota	13,864
Illinois	12,919
New York University	12,893
Ohio State	12,334
Michigan	10,646
Wisconsin	10,071
Washington (Seattle)	8,909
Texas	8,281
City College of New York	8,196
Harvard	8,111
University of California, Los Angeles	6,935
Louisiana State	6,823
Pennsylvania	6,608
Nebraska	6,544
Hunter College	6,506
St. John's	6,226
Chicago	6,170
Cornell	6,115
Boston University	6,025
Pittsburgh	5,866
Northwestern	5,833
Pennsylvania State College	5,575
Temple University	5,478
Syracuse	5,440
Indiana	5,344
Iowa	5,321
Purdue	5,298
Oklahoma	5,272
Yale	5,133
Brooklyn	5,000
Iowa State	4,843
Alabama	4,657
Kansas	4,465

Washington State	3,579
Whittier	467

Federal Grants to States for Assistance to Aged Persons.—Federal grants totaling \$2,724,615.10 for public assistance in California, Hawaii, Maryland, Michigan, Nebraska, Rhode Island, and Vermont were announced by the Social Security Board today.

The grants cover the period from January 1 to March 31, 1937. The amounts allotted to the states, the form of assistance for which each grant was made, and the number of individuals being aided under each plan in January, based on reports received for the past ten months, are shown in the following table:

State	Aid to	Grant	Estimated Number of Recipients
California	Aged	\$1,399,024.49	61,500

Health Officers' Training Course Scheduled at the University of California.—Continuing its drive to assist state health departments in training adequate public health personnel, the University of California has organized a second training course for sanitary inspectors, to be conducted on the University campus, under the direction of Dr. Karl F. Meyer, professor of bacteriology, from February 8 to May 4, 1937.

The first attempt in the United States to train sanitary inspectors on a large scale was made on the University campus during the summer of 1936, when forty-five men from nine western states and the Territory of Hawaii were put through a rigorous training course.

According to Doctor Meyer, the activities of the modern sanitary inspector are very broad. He must be able to meet men in all stations of life and be prepared to use diplomacy and ingenuity in enforcing public health laws. The training course is designed to develop a professional attitude and to teach the fundamentals of sanitation and the control of communicable diseases.

Eight weeks of the course will be given to lectures, conferences, laboratory practice, and group field trips. The final four weeks will consist of practical study in county and city health departments.

Certain entrance requirements will be enforced. Anyone interested in enrolling in the course may get further details from Karl F. Meyer, M.D., 3525 Life Sciences Building, University of California, Berkeley, California.

Prof. José Arcé of Buenos Aires Addresses San Francisco Chapter of Pan American Medical Association.—San Francisco had the honor of entertaining a distinguished visitor in the person of Prof. José Arcé of Buenos Aires, who arrived in this city on February 1 as the guest of the San Francisco Chapter of the Pan American Medical Association.

Rarely among confrères in any land has a physician attained the eminence in so many cultural fields and public welfare activities that is allotted this outstanding leader from South America's progressive republic. As president of the Argentine Chapter of the Pan American Medical Association, professor of surgery at the University of Buenos Aires, rector of the University, and senator of Argentina, Professor Arcé came to this country to promulgate medical Pan Americanism, to give scientific addresses and to conduct operative clinics before the chapters of New York, Washington, Los Angeles, San Francisco, etc. He also observed facilities for teaching graduate physicians in this country and addressed the students of the medical schools in the cities that he visited.

On Wednesday, February 3, at 8:15 p. m., Professor Arcé addressed the San Francisco Chapter of the Pan American Medical Association at the home of the San Francisco County Medical Society on "Preliminary Pneumothorax in Thoracic Surgery—The Importance of Its Use."

Thursday morning, February 4, at 9 a. m., he conducted an operative clinic under the auspices of the local chapter, performing a number of abdominal operations, including interventions on the gall-bladder, gastro-intestinal tract, and uterus. He also gave a scientific address before the faculty and students of the University of California Medical School on February 3 in Toland Hall, and addressed the faculty and students of the Stanford Medical School on February 5 in Lane Hall.

Professor Arcé was accompanied by his associates, Prof. Antonio Egeus and Prof. Adolfo Landivar.

Federal Old-Age Benefits.—With the Post Office Department now reporting receipt of 22,129,617 employee account number applications for participation in the federal old-age benefits program of the Social Security Act, a breakdown by states shows New York, with 3,433,631 applications, at the top of the list, the Social Security Board has reported.

This revised count of all applications on file in the 1,072 typing centers was made for the Board by the Post Office Department, and shows the totals for individual states. It supplements the Department's initial national total of 21,338,120 as of December 16, 1936, and represents an increase of 791,497 over the first report.

The Board stated that the present total of applications received should be considered as a progress report, for many thousands of Forms SS-5 are coming into post offices daily. The incompleteness of the present total is borne out by the fact that more than 24,000,000 workers are already represented on the employers' forms—known as "Employer's Application for Identification Number"—received at the Board's wage records office at Baltimore, Maryland.

Workers in seven of the leading industrial states account for more than half of the total applications, with New York first, and Pennsylvania second with 2,165,478. The next five are: Illinois, 1,680,059; Ohio, 1,469,837; California, 1,324,928; Massachusetts, 1,189,203; and Michigan, 1,109,435.

Totals by geographic divisions are: New England, 2,102,902; Middle Atlantic, 6,554,860; East North Central, 5,336,304; West North Central, 1,652,741; South Atlantic, 2,249,706; East South Central, 782,137; West South Central, 1,233,134; Mountain, 386,261; and Pacific, 1,730,117.

California Department of Industrial Relations: Report to Governor's Council—Safety Department.—The Industrial Accident Commission adopted the dusts, fumes, vapors, and gases safety orders, to be effective on December 28, 1936. These orders are the result of more than a year's study, many meetings of employers and employees with the Commission, and public hearings on the subject.

The orders require that all places of employment in which there is a hazard from dusts, fumes, vapors or gases shall be so arranged that these substances will either be prevented from being disbursed into the atmosphere breathed by the employees or, in those cases where this cannot be done, the employees will be furnished with approved respiratory equipment so that the air will be free from these substances. It is expected that by these means the dreaded disease silicosis will be eliminated from California.

The Mechanical Power Transmission safety orders and the revised logging and sawmill safety orders were also adopted, and became effective on January 1, 1937. Many meetings have been held between the employers, employees, and the Commission on this subject, and the orders as presented have the unanimous support of both employers and employees in the industries affected. These orders apply to every place of employment in which there is machinery and require that the belts, pulleys, sprockets, gears, shafting, etc., be guarded, so that there will be no hazard in their operation.

The revision of the mine safety orders is about complete. The orders are now in the hands of the printer, and the public hearings on these orders will be held in the near future.

The adopting of the new orders on dusts, fumes, vapors and gases, the adoption of the revised orders on logging and sawmills, and on mechanical power transmission and the proposed adoption of the mine safety orders will provide for places of employment the latest and best known means of preventing accidents in those industries and from the type of machinery covered by the orders.

Chairman T. A. Reardon and Commissioner Frank C. MacDonald of the Industrial Accident Commission appreciate the help that has been received from the employers and employees, and the independent consulting engineers who have given so freely of their time and knowledge in the preparation of these orders.

Federal Old-Age Retirement Benefits.—Under Treasury Department regulations, employers of one or more persons coming under federal old-age retirement benefits provisions of the Social Security Act are responsible for the filing of applications for an old-age benefit account number on behalf of their employees. The old-age benefits program went into effect January 1, 1937. . . .

Regulations No. 91 of the Bureau of Internal Revenue provide that employers after January 1, 1937, must make periodic reports to the Bureau in which the account number of each employee will be listed as the means of assuring proper credit to the employee's account for wages earned and taxes paid.

"Inasmuch as employers will eventually have to make sure that every employee has a Social Security account number in order to make required reports to the Treasury, it is evident," the Board's statement said, "that the more employees who file their applications now, the fewer will be the cases in which the employers will have to take action later."

Circumstances under which employers are required to fill out and file applications for employees are defined by Treasury Decision 4704 as follows:

"If an individual who is an employee on the last day of the period covered by any information return (see articles 402 to 405, inclusive, of Regulations 91) has failed to file an application for an account number on Form SS-5, the employer shall file an application for the employee on or before the tenth day after such last day. If an employee has failed to file an application on Form SS-5 prior to the date he attains age sixty-five, or the date he dies before attaining age sixty-five, or the date he leaves the service of the employer, the employer shall file an application for the individual on or before the tenth day after such date."

An employee, according to the Treasury Department's decision, must advise his employer as to the number of his account as soon as he receives it.

First International Conference on Fever Therapy.—The First International Conference on Fever Therapy will hold its sessions on March 29, 30, and 31, 1937, at the College of Physicians and Surgeons, Columbia University, New York City. The first day will be devoted to the discussion of physiology, pathology, and methods of production of fever. Dr. Frank W. Hartman, Henry Ford Hospital, Detroit, Michigan, is chairman of the committee arranging this section of the program, and Dr. Charles A. Doan of Ohio State University is secretary.

The second day is to be spent in the consideration of miscellaneous diseases treated by fever, such as chorea, rheumatic carditis, ocular diseases, arthritis, leprosy, meningococcus infections, undulant fever, tuberculosis, tumors, skin diseases, etc. This session will be arranged by Dr. Clarence A. Neymann, 104 South Michigan Boulevard, Chicago, Illinois, with the assistance of Dr. Frank H. Krusen, Mayo Clinic, Rochester, Minnesota, as secretary.

The morning of the third day is to be devoted to the consideration of syphilis. Dr. Walter M. Simpson, Miami Valley Hospital, Dayton, Ohio, is chairman of this section, which has as its secretary, Dr. Leland E. Hinsie, New York State Psychiatric Institute, New York City. In the afternoon of the same day, the treatment of gonorrhea by fever is to be discussed under the chairmanship of Dr. Stafford L. Warren, Strong Memorial Hospital, University of Rochester, Rochester, New York. The secretary of this committee is Dr. Charles M. Carpenter, Rochester, New York.

Ministries of Health from many countries have indicated their intention to send official representatives to the conference.

The official language of the conference is to be English.

Those desiring to participate are requested to communicate with the chairman of the Section in which they are interested. The manuscripts of all papers must be submitted to the appropriate chairman before February 1, 1937. Selection for the program will be made by February 15.

All who plan to attend the conference are urged to register promptly with the general secretary, Dr. William Bierman, 471 Park Avenue, New York City. The registration fee is \$15.

Federal Unemployment Assistance.—Grants totaling \$222,609.98 to cover state budgets for the administration of unemployment compensation laws in California, Kentucky, Minnesota, and Vermont were announced by the Social Security Board today.

The amount granted to California was for \$111,043.51, to cover the period from October 1 to December 31, 1936. The total amount that has been granted to California to date for this purpose is \$363,704.85.

Fifth International Congress of Hospitals.—At the congress in Rome, May, 1935, the International Hospital Association decided to hold the 1937 sessions in Paris. Previous sessions had been held in Atlantic City, Vienna, and Knocke Sur Mer, Belgium. The meetings will occur during the International Exposition, which will group the exhibits and products of more than fifty countries under the general caption, "Art and Technology."

Dr. Malcolm T. MacEachern of the American College of Surgeons is vice-president of the International Hospital Association. The Federation of the Hospital Unions of France has been designated officially by the Ministry of Public Health to cooperate with the International Hospital Association, and the program and arrangements for the congress are now being completed.

The meetings will be held at Paris from July 6 to 11, 1937, and will include visits to some of the large hospitals, the Cancer Institute, and the principal agencies engaged in public health work. At the time of the congress, scientific and pleasure tours will be conducted in various parts of France.

Persons attending the congress will be granted important reductions in rates when traveling on French and foreign railroads. The exposition authorities also will give special privileges to visitors.

The chairman of the Committee on Arrangements for the congress is M. Albert Chenevier, who is secretary-general of the Department of Public Assistance in Paris. Further information may be obtained from M. Chenevier, No. 3 Avenue Victoria, Paris IV, France.

Social Security Account Numbers.—Emphasizing that it is to the employer's and the employee's own interest to secure Social Security account numbers well in advance of the date they are actually needed for the periodic information returns required by the Bureau of Internal Revenue, the Social Security Board recently advised those employees and employers, who have not already done so, to file their applications immediately. At the same time, the Board stressed the fact that current non-possession of an account number is not a bar to the hiring of an employee. Application for account numbers should be made as soon after entering on duty as possible, however.

Bureau of Internal Revenue regulations, the Board stated, require employers to file periodic information returns giving their own identification numbers, and the name and account number of each of their employees who is required to have an account number. The regulations also require an employer to file an application for an account number for any employee who has failed to do so by the time the first information return is due. The time limit for filing of the first return, covering the period January 1 to June 30, 1937, is July 31.

In response to queries on how to obtain and file application forms at this time, the Board outlined the application procedure now being followed by employers and employees as well as by those who enter business or become employed in included employments in the future.

Employees' applications for account number—Form SS-5—will be available upon request at all local post offices, at the field offices of the Board, at offices of Collectors of Internal Revenue, and at the offices of the Board in Washington. They may be returned to local post offices through the employer, through a labor organization, or by mail or personal delivery.

Employers' applications—Form SS-4—may also be obtained at local post offices, field offices of the Board, from Collectors of Internal Revenue, and from the Social Security Board in Washington. Completed employers' applications are to be sent directly to the wage records office of the Social Security Board in Baltimore, Maryland.

The Centennial of the University of Louisville Medical School.—The University of Louisville Medical School is the second oldest medical school now in existence west of the Alleghenys and the oldest municipal medical college in the United States. It celebrates its centennial March 31 to April 3, 1937, at Louisville, Kentucky.

The Alumni are urged to make their plans now to attend their alma mater and participate in the celebrations. . . . The historic Old Kentucky Home at Bardstown and Lincoln Memorial at Hodgenville are also included in the itinerary. Mammoth Cave is within easy motoring distance for those who wish to visit this natural wonder. Lexington and the famous race-horse stables are but a short distance from Louisville and in the heart of the bluegrass region.

Postgraduate Course on Neuropsychiatry in General Practice.—The medical staff of the Menninger Clinic will conduct its third annual postgraduate course on Neuropsychiatry in General Practice, April 19 to 24, inclusive, at the Menninger Clinic, Topeka, Kansas. The course this year will include a brief introduction to the fields of neurology and psychiatry and a specific application of this knowledge to the large group of cases of psychoneuroses, psychoses and psychogenic and neurologic disorders which every physician meets in his daily practice. Suggestions made by those who took the course last year have been embodied in this year's program, in order to make it applicable to the most common practical problems of the physician.

As in previous years, several guest speakers, prominent in the fields of neurology and psychiatry, will appear at the evening sessions of the course.

Bureau of Vital Statistics: California State Board of Health.—*Births*—During July there were 7,416 births registered as against 7,056 during the corresponding month last year. This brings a total of 47,497 for the first seven months of 1936, as compared with 45,614 for the similar period of 1935.

Marriages.—There were 5,932 marriages in September of this year, bringing the total for the nine months to 44,938, while in September of 1935 there were 5,286 marriages with a nine months' total of 41,590, an excess of 3,348 marriages registered this year over last year (during the first nine months).

Deaths.—There were 6,042 deaths in May and 5,908 in June, as compared with 5,958 and 5,651 during the corresponding months last year. During the first six months of the year, there were 38,730 deaths, as compared with 36,787 in 1935 and 34,352 in 1934—an increase of 4,378, or 12.7 per cent, within the last two years, and of 1,943, or 5.3 per cent, over last year.

During the first six months there was an increase of 13.2 per cent among the epidemic diseases accounted for largely by an increase of 160.0 per cent in measles, 89.3 per cent in whooping cough, 52.8 per cent in influenza, and 62.5 per cent in dysentery, over the first six months' period last year. On the other hand, the degenerative diseases, cancer, diseases of the circulatory system, nephritis and senility, increased 3.3 per cent over the number recorded during the first six months last year. There were 2,143 infant deaths from January to June, 1936, an infant mortality rate of 53.5 per 1,000 live births, as compared with 1,952 deaths and a rate of 50.6 per 1,000 live births during the corresponding period last year.

Maternal deaths also show an increase in number, to be expected with the increased number of births. The increase is disproportionate, however, for while live births increased from 38,558 in 1935 to 40,081 in 1936, or 3.9 per cent, maternal deaths rose from 183 to 200, an increase of 9.3 per cent. The maternal death rate rose from 4.7 per 1,000 live births in the first half of 1935 to 5.0 during the first six months of 1936.

Suicides have increased from 763 to 798, an increase of 4.6 per cent, while external causes have increased 7.2 per cent from 2,812 during January to June, 1935, as against 3,015 in the same months of 1936. During the same period, pneumonia jumped from 2,100 to 2,469, an increase of 17.6.

LETTERS

Concerning Index Catalogue and Surgeon-General's Library.

LOS ANGELES COUNTY MEDICAL ASSOCIATION

Los Angeles, Calif., December 18, 1936.

To the Editor:—The medical profession considers that the Index Catalogue is one of the most valuable items for the advancement of the science of medicine, for the continued progress that the profession of medicine is making to protect the lives of our people, and to increase the health standards of this country. The Index Catalogue is of inestimable value.

The usefulness of the Index Catalogue is dependent upon the completeness of the files of medical publications contained in the library of the Surgeon-General's office—the greatest medical library in the world. To insure the value and usefulness of the Index Catalogue, the attached resolution adopted by the Los Angeles County Medical Association, with a membership of 2,400 doctors of medicine in Los Angeles County, was unanimously adopted at the annual meeting of the Association held December 17, 1936.

Respectfully yours,

E. VINCENT ASKEY, M. D.,
Secretary.

RESOLUTION

WHEREAS, The value and usefulness of the Index Catalogue is dependent upon the completeness of the files of medical publications contained in the library of the Surgeon-General's office—a public, national, medical library, the greatest in the world, serving in its present form of administration with satisfaction the medical profession and the medical libraries of our country; and

WHEREAS, In recent years the annual appropriation of the Congress has been wholly inadequate to provide sufficient funds to acquire the current medical books and periodicals issued throughout the world, so that they might be available for use throughout the country and for inclusion of the Index Catalogue; therefore be it

Resolved, That the Los Angeles County Medical Association, consisting of 2,400 members, urges Congress to appropriate annually to the library of the Surgeon-General's office an adequate sum for current medical books and periodicals and for the purchase of back publications lost during these recent years when the amount granted was grossly inadequate, thus depreciating the completeness and usefulness of the library's collection; and an additional sufficient sum annually, for as many years as may be required, in order to make for the greatest possible completeness of the collection and its Catalogue; and be it further

Resolved, That a sum be appropriated annually to defray the cost of printing regularly each year not less than one volume of the Index Catalogue; and be it further

Resolved, That a copy of these resolutions be spread upon the minutes of this Association and sent to the President of the United States, the presiding officer of both Houses of Congress, the Secretary of War, the Surgeon-General of the Army, and to CALIFORNIA AND WESTERN MEDICINE with the request for publication; and that these resolutions be published in the Bulletin of the Los Angeles County Medical Association with the request that the members send a copy to their local members of Congress requesting their support of these measures.

Concerning the fight against cancer.

To the Editor:—The American Society for the Control of Cancer has recently organized a Women's Field Army and in March will put on an extensive campaign of education throughout the United States and attempt to obtain enlistments. The campaign will be national in scope, and it is expected that the President will issue a proclamation. The Society has asked all local committees which it has built up during the last few years to cooperate with it at this time in broadcasting our slogan: "Fight Cancer with Knowledge." . . .

It seems quite fitting that at the close of the first decade of the New York City Cancer Committee's work, we can look forward to still greater educational achievements by our combined efforts in the decade to come.

Faternally yours,

(Mrs.) ELLA H. RIGNEY,
Publicity Adviser.

December 7, 1936.

FACTS ABOUT CANCER

The most recent group to mobilize its strength against a great and cruel scourge is the Women's Field Army of the American Society for the Control of Cancer. This nation-wide organization of the women of America will conduct a steady and relentless war to save, not to take human life. It is the kind of happy wholesome fight against fear and ignorance in which everyone can and should willingly take part.

The enemy is a cold and subtle killer which last year took more than 140,000 lives in the United States alone. It has been estimated that there are between three and five hundred thousand sufferers from this disease alive today. Perhaps half of them might be saved if knowledge of the signs and symptoms which might mean early cancer were given to them and if they were also strengthened by courage to act on that information without delay.

Concerning donation to Lane Library: Letter of thanks.

STANFORD UNIVERSITY
OFFICE OF THE PRESIDENT

January 4, 1937.

My dear Doctor Warnshuis:

May I through you thank the members of the California Medical Association on behalf of the University for the recent check for \$122.50 to be credited to the Lane Library Book Fund.

With much appreciation and every good wish for the coming year, I am

Faithfully yours,
RAY LYMAN WILBUR,
President.

Concerning proposed legislation on milk.

CITY AND COUNTY OF SAN FRANCISCO
DEPARTMENT OF PUBLIC HEALTH

January 14, 1937.

To the Editor:—The enclosed copy of a letter which I have addressed to the members of the California State Legislature from San Francisco is forwarded to you that you may know of these circumstances, and particularly of my reaction to the proposed legislation referred to.

Sincerely,

J. C. GEIGER, M. D.,
Director of Public Health.

CITY AND COUNTY OF SAN FRANCISCO
DEPARTMENT OF PUBLIC HEALTH

January 14, 1937.

The Members of the California Legislature from San Francisco, Addressed.

I wish to invite your attention to two bills now before the Legislature: Heisinger A. B. 50 and Thorp A. B. 77. The passage of these bills will be inimical to the public health of San Francisco particularly, in that they are destructive to our local milk ordinance and milk inspection service.

Under our milk ordinance, the entire supply comes from non-reacting tuberculin-tested herds and is of but two grades: "Grade A pasteurized" (99.5 per cent) and "Certified" (raw) (0.5 per cent). The proposed legislation will remove these safeguards to force into the San Francisco market raw milk of other grades, including the so-called "Guaranteed" and others lower, as well as pasteurized grades of milk from non-tested and presumably tuberculous herds.

The placing of all milk inspection in the State undoubtedly will result in inadequate remote control and lower

standards than exist in San Francisco today. These proposals are basically wrong, from the viewpoint of efficient public health administration, not only for San Francisco, but for California.

These proposed legislative instruments are a distinct menace to public health, for they will open up channels of infection for tuberculosis and other diseases, especially in infants and children. I point these situations out to you that there may be no letting down to safeguards built up over a period of years, particularly since they may mean the difference between health and happiness on the one hand, and disease and death on the other. The passage of these bills would be a public health tragedy.

Sincerely,

J. C. GEIGER, M. D.,
Director of Public Health.

Concerning reorganization of Franklin Hospital medical staff.

To the Editor:—The medical profession in and about San Francisco no doubt will be interested in the following news item:

On November 4, 1936, at a general meeting of the German General Benevolent Society, the constitution and by-laws of the Society were amended to discontinue taking members with medical service. A second amendment was also unanimously passed at this meeting establishing the policy of taking in associate or group associates who shall receive, on periodic payment of dues, hospitalization. The benefit to be received by the associate or group associates is limited strictly to hospitalization. Laboratory and x-ray work are excluded because these services are held to be the practice of medicine. The associate or group associates shall have free choice in the selection of their physician.

The Society is legally bound to continue to take care of their present members, particularly those members possessing life certificates. The Board of Directors is strongly urging the present members to change their status to that of associate members.

This action removes the German General Benevolent Society as a potent future competitor of the medical profession. This organization has been active since 1852, and the Board of Directors and voting members are to be commended for the about-face at a time when so many agencies are encroaching upon the private practice of medicine. They cooperated completely with the suggested medical policy.

Likewise, if and when, the San Francisco County Medical Society and/or the local hospitals establish a constructive collective hospitalization program, Franklin Hospital will be ready to cooperate 100 per cent.

Yours very truly,

LEROY BROOKS,
Chief of Staff, Franklin Hospital.

Explanatory Note to Above Letter.—The German General Benevolent Society in San Francisco has given to its members, for seventy-five years, medical, surgical, and hospital care on the periodic payment of dues. The Society owns and operates the Franklin Hospital in San Francisco. The patient's choice of physician has been limited to the appointed or closed staff of the Franklin Hospital. The staff has given its professional care to members with practically no compensation.

On November 24, 1936, at a general meeting of the German General Benevolent Society, the by-laws were amended to discontinue taking members with medical care. At the same meeting, a second amendment to the by-laws was passed offering associate members hospitalization without medical care, with free choice of physician on a periodic payment plan. By this action the Franklin Hospital is no longer in direct competition with the medical profession.

The Board of Directors and voting members are to be commended for their cooperation at a time when so many agencies are making inroads into the private practice of medicine. They have set an example which could well be followed by other organizations.

MEDICAL JURISPRUDENCE†

TAX PROVISIONS OF THE FEDERAL SOCIAL SECURITY ACT AND THE CALIFORNIA UNEMPLOYMENT INSURANCE LAW

By HARTLEY F. PEART, ESQ.
San Francisco

The Federal Social Security Act was passed by Congress and approved by President Roosevelt August 14, 1935. This act is in reality a series of acts, and for the purposes of this discussion we shall deal specifically with but two portions of the Act:

I. OLD-AGE BENEFITS

In order to provide for old-age benefit payments or pensions for employees who have reached the age of sixty-five years, the Act provides for:

1. A wage tax on employees, commencing on January 1, 1937. For the first few years of the Act the tax is levied at the rate of one per cent of the wages earned, and progresses upon a graduated scale until the tax becomes three per cent of the wages in 1949, and continues at that rate thereafter unless the Act is subsequently amended. This tax is to be collected by the employer by deducting the amount of the tax from the wages of his employee as and when paid. The employer is made liable for the amount of the tax. The amount of this tax may not be deducted by the employee in computing his net income for regular income tax purposes.

2. An excise tax is levied upon the employer's payroll and at the same rates as above, with the following exception: Any wages paid to an employee in excess of \$3,000 a year are not considered by the employer in determining and deducting the employee's tax or in determining the tax which the employer is to pay. The sum collected by the employer, together with the tax payable directly by such employer, is to be collected by the Bureau of Internal Revenue and paid into the Treasury of the United States, where an "Old Age Account" is to be set up.

Certain types of labor are exempted from the provisions of the Act. Agricultural labor, domestics, casual labor, employees of the United States, any state, counties, municipalities and subdivisions or instrumentalities thereof, officers or members of the crew of a vessel documented under the laws of the United States or any foreign country, individuals over the age of sixty-five, and employees of any organization operated for religious, charitable, scientific, literary, etc., purposes, no part of the earnings of which inure to the benefit of any private person, are all exempted from the provisions of this act.

All employers and all employees, with the exception of those included in the exempted fields noted above, are included within this act, regardless of the number of individuals employed, and it is to be remembered that the money so paid into the Federal Government is to be used to create old-age benefits for those employees who are included within the provisions of this act and whose employers were liable for the tax provided by this act to the Federal Government. The amount of the monthly benefit which becomes payable upon the employee attaining the age of sixty-five years and retiring, depends, of course, upon the amount of money which has been paid into the United States Treasury by reason of the wages earned by him. The minimum and maximum monthly payments are \$15 and \$85 per month, respectively.

II. FEDERAL UNEMPLOYMENT INSURANCE

The second taxing measure of the Social Security Act with which we are here concerned is sometimes termed the "Tax on employers of eight or more." It is also commonly termed the "Federal Unemployment Insurance Tax." In order to provide a form of unemployment insurance, the Social Security Act further provides for a tax on employers of eight or more. This tax is separate

† Editor's Note.—This department of CALIFORNIA AND WESTERN MEDICINE, containing copy submitted by Hartley F. Peart, Esq., has been established by the California Medical Association Council. Each issue will contain excerpts from and syllabi of recent decisions and analyses of legal points and procedures of interest to the profession.

from and in addition to the tax previously discussed which was for old-age benefits. This tax is paid by employers and is not deducted from the employee's wages. The tax was at the rate of one per cent on the employer's total payroll between January 1, 1936, and December 31, 1936. It will be two per cent in 1937 and three per cent in 1938 and thereafter. This tax applies only to employers who on each of twenty days during the calendar year, each day being in a different week, employed eight or more persons. The money so collected is to be paid into the Treasury of the United States, where a fund known as "The Unemployment Trust Fund" has been created. Under the provisions of this statute, the following employers are exempted: Agricultural labor, domestics, service performed as an officer or member of the crew of a vessel on the navigable waters of the United States, service performed by an individual in the employ of his son, daughter, or spouse, and service performed by a child under the age of twenty-one in the employ of his father or mother, service performed in the employ of the United States Government, a state, county, municipality or political subdivision thereof, or of an instrumentality thereof, service performed in the employ of an organization operated exclusively for religious, charitable, etc., purposes, where no part of the net earnings inure to the benefit of any private individual. This federal act provides that if the state wherein the employer's place of business is situated adopts a suitable unemployment insurance plan, the employer may credit against his payment to the Bureau of Internal Revenue that amount of state tax which will not exceed 90 per cent of the federal tax. The purpose of this provision was designed to encourage the enactment of state laws patterned after the federal act. California has adopted such a law, which is known as the "California Unemployment Insurance Law." This is the third taxation statute under discussion here and will be considered in more detail below. Just how the funds collected by the Federal Government under this second taxing measure of the Social Security Act will be used for the benefit of unemployed individuals is not specifically set forth.

The federal act provides that those states which adopt their own plan, and which has been approved, will be granted federal money with which to finance the administration of the state plan.

CALIFORNIA UNEMPLOYMENT INSURANCE

The third related tax measure is entitled the "California Unemployment Insurance Law." This act was placed upon the statute books of this state on June 25, 1935, to conform to the general plan for unemployment insurance which was to be suggested to the several states by the federal act. Section 2 of the California act provides:

This act is enacted as a part of a national plan of unemployment reserves and social security and for the purpose of assisting in the stabilization of unemployment conditions. The imposition of the tax herein imposed upon California industry alone, without a corresponding tax be imposed upon all industry in the United States, would by the corresponding penalty upon California industry defeat the very purposes of this act set forth in Section 1.

It is further provided that the Act shall take effect only upon the adoption of legislation by the Federal Government providing for an unemployment insurance tax. The California act and the federal act are very similar. The same employers are taxed, to wit: those employing eight or more individuals on each of twenty days during the calendar year, each day being in a different week. Its benefits extend to the same employees, to wit: those employed by the employers last mentioned. Practically the same occupations are excluded. There is an important difference, however. The California plan is financed by both employers and employees. The employers' tax rate was fixed at .9 per cent for 1936, 1.8 per cent for 1937, and 2.7 per cent for 1938 and thereafter. These figures were chosen so as to enable the employer to take advantage of the credit allowance provided by the federal act. Consequently, a California employer being taxed under both the state and federal acts will not have to pay more than the percentage of his total payroll which is required by the federal act to satisfy both taxes. In addition, each employee is taxed .5 per cent of his salary

for 1936, 1 per cent of his salary for 1937, and at the same rate for his salary for 1938 and thereafter. The law provides that employees shall not pay more than one-half of the amount paid by the employers. As a result, the employee's tax for 1936 was reduced to .45 per cent from .5 per cent. As in the case of federal tax for old-age benefits, the employee's share of the tax is to be withheld from the employee's wages by the employer and paid by him. This money is to be paid into an "unemployment administration fund."

There has been considerable discussion as to the constitutionality of each of the three taxing measures which have been briefly discussed above. As yet, there has been no decision by the Supreme Court of the United States as to the constitutionality of the Social Security Act and the two taxing measures therein provided, namely, the old-age benefit provision and the unemployment insurance provision. However, the Supreme Court of the United States has passed upon the constitutionality of the New York Unemployment Insurance Law, which is similar to the Unemployment Insurance Act of California. The United States Supreme Court, with eight of the nine judges sitting, failed to reach a decision, as the judges were equally divided in their opinions as to the constitutionality of the New York law. Consequently, the decision of the New York Court of Appeals, which court held the Act constitutional, had to be affirmed. No written opinion was rendered by the United States Supreme Court.

The Supreme Court of the State of California recently had occasion to pass upon the validity of the California act. In the case of *Gillum vs. Johnson, Treasurer of the State of California, et al.*, 92 Cal. Dec. 647, the court concluded that the Act was constitutional and ordered the defendants, the State Treasurer, the State Controller, and the Unemployment Reserves Commission of the State to comply with the provisions of the Act.

Cases involving the constitutionality of the Social Security Act have been filed in several of the lower federal courts, and within the near future we may expect a decision from the Supreme Court of the United States in regard to the constitutionality of this federal act.

SPECIAL ARTICLES

HOBBY EXHIBIT: LOS ANGELES COUNTY MEDICAL ASSOCIATION

"Interests far from the operating theater and the diagnosis chart are indicated in the current hobby show of Los Angeles County Medical Association members.

"Held in the Association's lounge, 1925 Wilshire Boulevard, the show will be open daily from 9 a. m. to 9 p. m. during the week of January 11. In charge are Dr. E. Vincent Askey, secretary, and S. K. Cochems, executive secretary."

The above are the opening paragraphs of an article which appeared in the Los Angeles *Times*.

Members of the California Medical Association will be able to appreciate how generous was the response to the request to members that they place on exhibition their "hobby collections" and own handiwork for the pleasure of fellows, by perusing the list of exhibits which follows and noting their character, as evidenced in the illustrations. The first annual hobby show of the Los Angeles County Medical Association was voted a great success. List of exhibits follows:

Howard Andrews, M.D.

Acclaimed as one of the finest collections of firearms in United States history; a display of some two hundred weapons for holster, belt and pocket, including the so-called pepper-box weapons, flintlock pistols, heavy dragoon models, the early pocket revolvers, and an exceptionally fine display of Deringer pistols, including a duplicate of the one used in the assassination of Abraham Lincoln.

Stephen G. Seech, M.D.

A display of rare Austrian stamps—just a small portion of Doctor Seech's collection.

Paul K. Selve, M.D.

Landscapes in oil. Illustrating that art is not the least of our members' attainments.

Fig. 1.—"Hobby Show": Los Angeles County Medical Association. Photograph of southeast corner of Lounge Room in Headquarters Building.

Katherine M. Close, M.D.

A seascape in tempera—a lovely bit of color and composition.

Philip S. Doane, M.D.

A carved bench and various items of beautifully carved work.

Randall Hutchinson, M.D.

Bead work. Exceptional design and workmanship.

Arthur Bowen, M.D.

Hand-tooled leather, including an exceptionally beautiful desk set, book covers, card cases and boxes.

Joseph Savage, M.D.

Heads in charcoal that show the work of a true artist. Doctor Savage also had on display an exquisitely made ship model, illustrating his other hobby.

Paul Z. Hebert, M.D.

An unusual technique of pictorial art in glass.

Saul Robinson, M.D.

A series of oils that lend art value and dignity to the display.

Sven Lokrantz, M.D.

Two exhibits, entitled "Fantasia" and "Land of Make Believe," in relief art. Two items in the display that created a great deal of attention and which illustrate many hours of painstaking work—truly exquisite offerings.

H. O. Bames, M.D.

A display, through stamps and literature, illustrating that Vienna is but three days away from Los Angeles.

F. H. Brandt, M.D.

The pencil is not a forgotten implement with which to create art. This is exemplified in the display of penciled landscapes by Doctor Brandt.

Salvatore R. Monaco, M.D.

Pottery of unusual design and beauty. A hobby that must be of great interest.

Fig. 2.—"Hobby Show": Los Angeles County Medical Association. Photograph of northwest corner of Lounge Room in Headquarters Building.

Fig. 3.—"Hobby Show": Los Angeles County Medical Association. Photograph of southwest corner of Lounge Room in Headquarters Building.

Lloyd Mills, M.D.

Two concertos for piano and orchestra and a rhapsody for two pianos.

Lowell S. Goin, M.D.

Excerpts from "Mass, in E flat." A composition by Doctor Goin.

George Laton, M.D.

Two compositions, entitled "Cavaliers" and "Prayer" (Masefield—Poems), Volume I.

A. Marians, M.D.

Unusual specimens of colored photography.

Harold Lincoln Thompson, M.D.

The camera, as an instrument for art, has long been recognized. Doctor Thompson illustrates what may be done with this mechanism in the creation of true art. His landscapes, his portrait of a dog, and a study of Lincoln in the Lincoln Memorial at Washington, can only be appreciated by being seen.

Charles L. Lowman, M.D.

Unusual stamps from Doctor Lowman's extensive collection.

Harold Dewey Barnard, M.D.

Those who know Doctor Barnard might expect a large mounted rainbow trout, a big bear skin, an exceptionally fine deer head, and other items that delight the heart of the hunter, and these were all displayed.

Norval William Haddow, M.D.

Doctor Haddow's hobby is "climatology." Graphs to illustrate his interest in this hobby were displayed.

Harold F. Whalman, M.D.

Motion pictures in colors were shown at stated intervals during the exhibit by Doctor Whalman, who proved that colored motion pictures are not things for only commercial enterprise.

E. R. Lambertson, M.D.

California landscapes in oil, with the color and sunshine and atmosphere that is California.

Cora Smith King, M.D.

A small portion of an extensive collection of pressed plant life of the West.

Robert H. Kennicott, M.D.

The oils of Doctor Kennicott brought to the "Hobby Show" some of the modern spirit in art in still life and figures.

Marcia A. Patrick, M.D.

An oil in brilliant colors and a California seascape, both adding dignity and interest to the display.

Clinton D. Hubbard, M.D.

We are sorry indeed that space forbids Doctor Hubbard displaying his complete collection of sea shells from the seven seas. It is hoped that next year the entire collection may be shown. To say the least, it is most interesting and unusual.

Hans von Briesen, M.D.

Whittling is what Doctor Briesen entitled his exhibit; an exhibit of four lithographs of old paintings, the frames and the lithographs processed to give an antique effect. These attracted a great deal of attention. Also several carved wooden figures, including a box of chessmen.

Jonas C. Kopelowitz, M.D.

Wood working is Doctor Kopelowitz' hobby. On display he has various items, including a specially constructed card-table top and a toy aeroplane.

George Dock, M.D.

A series of photographic enlargements of some of the greater bits of scenery in this country. One of exceptional interest is the picture of a terrace and garden at Sir William Osler's house, 13 Norham Gardens, Oxford, England.

James Reeve Dean, M.D.

Precision rifle shooting holds Doctor Dean's interest. On display were various telescopes and precision rifles, together with the ammunition used.

Cyril B. Courville, M.D.

Firearms of the Civil War. Collectors of firearms show much interest in this complete collection. Weapons used by both the North and South are on display.

Frank E. McCann, M.D.

Pictorial photography. Four landscapes and an exceptionally fine study of an Indian head.

Raymond L. Schultz, M.D.

Intricate surgical instruments made by himself.

Orrie Edw. Ghrist, M.D.

Doctor Ghrist enjoys travel to far places. Several years ago he made a trip to the South Sea Islands. A very fine collection of stereopticon pictures, which he took himself, were on display for the enjoyment of visitors to the exhibit, with a stereopticon.

Henry G. Bieler, M.D.

Doctor Bieler is an artist in modeling and sculpturing. His pieces, modeled in wood, are of exceptional interest.

Louis K. Guggenheim, M.D.

Landscapes in oil. More of Doctor Guggenheim's work would have been welcome. One study in particular shows a very fine appreciation of the value of color.

Robert A. Campbell, M.D.

Wood working is shown to be truly an art in the display of Doctor Campbell. Various types of beautiful woods have been carved into beautiful things from the turning lathe of this member.

Edward L. Sudlow, M.D.

Doctor Sudlow's display—just a few old books—but what books! Every older visitor to the exhibit stopped at that display. A collection of McGuffey's Readers. Some of you may remember the first reader. It starts off with a picture of a dog: "The Dog, The Dog ran."

Frank B. Young, M.D.

An exhibit of comparative pathologic and physiologic osseous conditions. This display is of exceptional interest to the scientifically minded.

John W. Nevius, M.D.

An unusual and beautiful book, containing tuberculosis stamps collected from all parts of the world.

THE PRACTICE OF MEDICAL SPECIALTIES IN HOSPITALS*

A Report to the Medical Problems Group of the San Francisco Medical Society

The problem of the proper ethical and legal relationship between hospitals and certain medical specialties has been a vexatious one. It was left largely to individual action until recently, when the question of organized medicine approving the various relations was forced by the many schemes for hospital insurance. It has been argued that the specialists involved should not use the lever of the recognition of hospital insurance schemes as a means of solving their problems. That would certainly be true were it not for the fact that organized medicine is being asked for the first time to officially approve of certain practices which are probably both illegal and unethical. The fundamental problem has no connection with insurance, but concerns the legal and ethical aspects of the practice of certain medical specialties in hospitals.

CORPORATIONS AND MEDICAL PRACTICE

Let us first consider the legal aspects of the problem. There have been definite legal decisions regarding the right of corporations to practice medicine. The most recent one is that involving the Pacific Employers' Insurance Company. In that decision the court held that the company could not circumvent the law by employing licensed physicians to practice for it. A similar decision was that in the case of *People vs. United Medical Service,*

Inc., N. E. 157, which the Supreme Court of Illinois handed down on February 14, 1936. The court, in unmistakable language, proscribed corporations from practicing medicine even though they attempt to do so through the medium of salaried employees who are licensed physicians. The Supreme Court of the State of California has said: "That a corporation may not practice law, medicine, or dentistry, is a settled question in California." (*Parker vs. Board of Dental Examiners*, 216 Cal. 285, 14 P. (2d) 67.)

RADIOLOGY

That the practice of radiology is the practice of medicine is also a settled question. The House of Delegates of the California Medical Association in May, 1936, adopted a resolution reading in part:

Resolved, That radiology and pathology, being in all of their several parts and subdivisions the practice of medicine, etc.

The House of Delegates of the American Medical Association in May, 1936, adopted a committee report containing the following:

It reiterates the principle enunciated by the House of Delegates at Cleveland in 1934, "That the practice of radiology, whether for diagnostic or therapeutic purposes, constitutes in fact the practice of medicine." The action of the House of Delegates in 1925, establishing a section on radiology, confirms this principle.

Since radiology is the practice of medicine, it is illegal for hospitals to engage in the practice of it. However, some hospital administrators maintain that they are not practicing medicine when they manage only the business side and arrange with a licensed physician to provide the professional services. Let us look carefully into this contention. The practice of medicine is a contract between a patient who needs medical services and a doctor who can render it. Because that service is a personal as well as a professional one, the laws of various states have decreed that no person or corporation may come between the doctor and his patient. If the patient pays his money to the hospital, the contract is between the patient and the hospital, the latter agreeing to furnish the radiologist's service. The hospital is entering as a third party. The physician owes his allegiance to the hospital which employs him, and he can owe but a secondary and divided loyalty to the patient.

Very definite legal opinion is available on this subject. The Supreme Court of the State of California, in the case of *Painless Parker vs. Board of Dental Examiners*, made the following comments in answer to the contention that there is a distinction between the practice of dentistry and the purely business side of the practice:

The law does not assume to divide the practice of dentistry into that kind of departments. Either one may extend into the domain of the other in respects that would make such a division impractical if not impossible. The subject is treated as a whole. If the contention of appellant be sound, then the proprietor of the business may be guilty of gross misconduct in its management and violate all standards which a licensed dentist would be required to respect and stand immune from any regulatory supervision whatsoever. His employee, the licensed dentist, would also be immune from discipline upon the ground that he was but a mere employee and was not responsible for his employer's misconduct, whether the employer be a corporation or a natural person. On grounds of public policy such a condition could not be countenanced.

No one would dispute the right of any person to own a dental office equipment. The question most appropriate here is whether the thing owned is used for a given purpose by a person lawfully entitled to so use it. Ownership is not the absolute test of the right of use.

The court went on to say that if Parker's contention is sound, the Dental Practice Act is impotent to accomplish the purpose it was intended to serve, namely, to promote the safety, health, and welfare of the people of the State.

The legal side of the issue can be righted only by one method. The physician who provides the medical service must make the contract with the patient, and must collect the fee in such a way that the patient knows he is paying that physician.

REIMBURSEMENT TO THE HOSPITAL

Such being the case, how is the hospital to be reimbursed for the use of its space, equipment, materials,

* This report was made by a committee consisting of Robert Stone, M.D., Randolph G. Flood, M.D., Emery M. Seeburt, M.D., Leon O. Parker, M.D., president of the Medical Problems Group, and Frank Hand, M.D., secretary of Medical Problems Group, and submitted for publication by the committee.

etc., or whatever part of them it furnishes? At the present time there are three types of arrangement by which hospitals are reimbursed: First, salary—the hospital taking the money and paying the physician a stated percentage of the gross or net income of the department. Second, commission—the hospital taking the money and paying the physician a stated percentage of the gross or net income of the department. Third, reimbursement—the physician collecting the fees and paying the hospital an amount which is in relation to the space, etc., provided, *not* in relation to the income of the physician. Assuming that the fees are collected by the physician, the legal aspects are satisfied, but what about the ethical aspects if the money is turned over to the hospital to be divided on any of the above bases?

AMERICAN MEDICAL ASSOCIATION CODE OF ETHICS

Chapter 3, Article 6, Section 4, of the Code of Ethics of the American Medical Association states:

It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group, or individual, by whatever name called, or however organized, under terms or conditions which permit a direct profit from the fees, salary, or compensation received to accrue to the lay body or individual employing him. Such a procedure is beneath the dignity of professional practice, is unfair competition with the profession at large, is harmful alike to the profession of medicine and the welfare of the people, and is against sound public policy.

In elaborating on this the Bureau of Medical Economics of the American Medical Association states:

Where physicians become employees and permit their services to be peddled as commodities, the medical services usually deteriorate, and the public, which purchases such services, is injured.

From this we deduce that any arrangement which permits the hospital to profit from the "medical fees" is unethical. Whatever arrangement is made must be based on the space, equipment, etc., provided, not on the medical fees collected. The salary arrangement is thus definitely unethical. It makes whatever profit the hospital receives directly proportional to the fees collected.

COMMISSION OR PERCENTAGE BASIS

The commission or percentage basis is equally unethical on the above grounds. The hospital stands to profit directly in proportion to the fees collected. It is equally unethical on the ground of fee-splitting. When a hospital is on a percentage basis, it is directly interested in the amount of practice done. It is not limited by the rules of medical ethics and can go out and advertise its equipment, or even the professional attainments of the physician it employs. This has been done by some institutions, and so far as the physician is concerned, constitutes a voluntary or involuntary solicitation of patients. Such a percentage basis constitutes in essence an agreement by the physician to pay the hospital a definite amount for each patient it secures for him.

The remaining method is that of reimbursement on the basis of the full cost to the hospital of providing the department. In such an arrangement the physician agrees to pay the hospital a stated sum for the use of the space, etc., which it provides. This amount should be based on the value of the space occupied, just as it would be for space in an office building, plus items to cover whatever other expenses the hospital has in connection with the operation of the department. A proper amount can thus be fixed whether the physician is provided with space alone and provides everything else himself, or is provided with space, equipment and supplies by the hospital. If the hospital provides everything, it could base the amount charged on the number of patients examined. In other words, the radiologist would pay the hospital a stated amount for each examination performed. The amount paid by the radiologist bears no relation to the fee he collects. Can you imagine a hospital collecting an operating-room charge based on the amount of the fee collected by the surgeon?

WHO SHALL PRACTICE RADIOLOGY IN THE HOSPITAL?

Let us look briefly at the problem of who is to practice this specialty in the hospital. The license of a physician and surgeon gives to the person so licensed the right to

practice any branch of the healing art. The State does not recognize specialists. Hence, under the State law any physician who so desires can make x-ray examinations, give x-ray treatments, make tissue examinations, etc., being limited only by his own conscience. Organized medicine, however, steps in to try to elevate the standards of medical care above that required by State law. The American College of Surgeons and the American Medical Association have specified that, if a hospital desires to be recognized as approved for interne training, it must have the radiologic and pathologic services performed by a duly recognized specialist. Hence, so far as approved hospitals are concerned, only qualified specialists can render these services. In *small* hospitals, or those that do not wish to be recognized and classified, any physician who is willing to assume full responsibility for all the acts performed and for the diagnosis or partial diagnosis rendered, can do so. It is to be borne in mind here that the courts have held that "delegated acts, done by a lay person helping a doctor, must be pure mechanical functions not requiring the exercise of judgment. The physician is responsible for all that is done, and must exercise all the judgments. A doctor cannot delegate the 'right to practice medicine,' but can accept lay assistance which is given directly in accordance with the instructions of the doctor." In those hospitals not desiring to be recognized, any specialty can be practiced by any physician who is willing to accept full responsibility for all acts done.

EMPLOYMENT OF LAY ASSISTANTS

In view of the fact that every physician is responsible for the delegated acts of his lay assistants, it is essential that the radiologist shall have the right of selecting his lay help. This involves the determination of the conditions of their employment. Of course, it is assumed that all appointments are subject to the approval of the superintendent. In the case of *Painless Parker*, cited above, the Supreme Court of the State of California ruled that it is impossible to separate the business and professional parts of the practice of dentistry. How much harder it is to separate the technical and professional parts of the practice of medicine! They are intimately bound up. To be legally correct, the technicians must be directly responsible to the physician for all acts they perform. The physician, not the hospital, is legally responsible for their acts.

OTHER FACTORS

One further point in connection with the reimbursement scheme presents itself. Many hospitals claim that they are entitled to an excessive amount on the grounds that they are giving a monopoly, a ready-made practice, and a certain amount of good will. Let us discuss these features item by item.

It is true that most hospitals have only one roentgenologist and that he gets all the practice in that hospital. This condition has arisen because of the necessity for the supervision of the acts of technicians by a licensed practitioner. If the x-ray examinations were to be done as surgery is done, only when the roentgenologist were present, and if roentgenologists were to run about from one hospital to another as do surgeons, then they would have to charge more for their services, because each act would take much more of their time. Moreover, each and every doctor on the staff of a given hospital wants the roentgenologist to be present at the hospital at the same time as he is there, so that he can talk to him relative to his patient. He wants a full consultation, not just a written report. Hence, it has seemed expedient for these specialists to limit their practices to one hospital and be present as much of their time as the work there warrants. Thus, not only does the hospital give a monopoly *but it also asks the monopoly* of the particular specialist's time, either full time or on demand. Under the proposed plan there is no necessity for a monopoly if the staff does not desire to monopolize one specialist's time. They could appoint as many specialists in any one specialty as they desired, and each of these could pay the hospital an amount proportional to the use they made of the department or to the number and kind of examinations done or treatments given.

The idea of furnishing a ready-made practice applies only to hospitals who have as roentgenologist a young man just out of training, or a failure type who has not

been able to build a practice of his own. Most hospital staffs should, and do want, as consultant roentgenologists men who have established reputations and whose abilities are known. Such men can have a practice outside as well as inside a hospital. Instead of getting from the hospital a ready-made practice, they are giving to the institution the added prestige and good will of having them on the staff. They are a drawing card for the hospital, inasmuch as other practitioners are going to take their patients to that hospital where they can get satisfactory consultations. Moreover, few hospitals have enough work originating in the hospitals to keep a well-qualified man occupied for his full time, or to keep their equipment and space in use enough to repay them for the investment they have made. Hence, non-hospitalized patients must be attracted to the departments. This is accomplished only by having a physician in charge who commands the respect of his fellow practitioners. It is he, not the hospital, that attracts this kind of practice.

With regard to the question of good will, the same arguments apply as above. The hospital may provide a little good will to a young man just starting; but once he is established he provides good will to the hospital. Would any physician who "buys" a practice consider it necessary to continue to pay a good-will premium to the doctor from whom he bought it, after he, the purchaser, has once established himself?

HOSPITALS MUST PROVIDE GOOD RADIOLOGIC SERVICES

On the other hand, it might equally well be argued that it is absolutely necessary for a hospital to provide the means of good radiologic services, if that hospital is to be patronized by physicians who might bring their patients to it. It is to be remembered that the paying patients in a hospital are not the patients of that hospital *but of the physicians* who bring them there. If necessary, the hospital might have to pay a premium to a good, well-qualified, well-established specialist for devoting his time to work in that hospital, thereby helping to keep the beds filled.

PLACEMENT OF RADIOLOGISTS ON HOSPITAL STAFFS

One more point remains to be considered, namely, the method of selecting and appointing to the staff the particular specialists concerned. Very few physicians are consciously aware of the fact that most roentgenologists are now virtually employees of the hospital. While the hospital management may ask for a committee of the staff to help them select the specialist concerned, the actual appointment is not made by, or even on advice from, the governing medical board, but by the superintendent. All too frequently, as is to be expected under such an arrangement, the appointment is made, not on the basis of professional attainments, but on the amount of money the hospital is to receive. Analyzed on the basis of the facts revealed in this report, this means that the hospital management appoints the physician who is willing to give them the biggest percentage of the fees he collects. This arrangement places the specialist concerned in a very unprofessional position. That man who adheres most strongly to his ethical professional rights stands the least chance of being employed.

A REMEDY

This situation can be remedied by the professional staff insisting that all physicians be appointed to the staff in the same way. If the hospital management provides the space, etc., required on the basis of their financial investment in it, then that amount would be the same whomsoever was appointed. They would be interested then in having the medical board appoint that specialist whom the board considered most qualified. The specialist selected would be on the same professional status in the hospital as any other physician. He would not be an "employee allowing the hospital to peddle his professional services as a commodity."

Likewise the termination of the appointment of each specialist should be in the hands of the medical board.

RECOMMENDATIONS

In conclusion we recommend the following as the legal, ethical, and professional arrangement for the practice of certain specialties in a hospital.

1. The specialist or specialists concerned should be selected as are the other members of the professional staff,

namely, by the executive medical committee, on the basis of their qualifications, abilities, and professional standing.

2. They should then be appointed to the staff in the same manner as any other member of the staff.

3. The selected physician or physicians should then make arrangements with the hospital management to reimburse them on the basis of the value of whatever space, equipment, etc., the hospital is to provide. The radiologist, being legally responsible for the acts of his lay assistants, shall control the conditions of their employment.

4. The specialist so selected should make all contracts with the patients and make arrangements for the collection of his own fees.

5. The appointment should be terminated only for cause, as determined and recommended by the governing medical board by whatever name called.

6. If agreeable to the staff, and practicable, there can be no objection to the appointment of several specialists in the specialty, each to pay the hospital a pro-rated amount based on the number of examinations made or treatments given.

7. In those institutions where charity work is done, the radiologists must give their services free as do the other members of the staff. The hospital must bear the cost of such work (other than professional costs) as they do in the other departments.

EXAMPLE

8. Example 1. A hospital needs a radiologist on its staff. The medical executive committee of the hospital selects and recommends for appointment Dr. A. The Board of Trustees or similar body makes the appointment. Dr. A and the hospital management then determine and agree upon the monthly or per examination cost to the hospital of handling patients in the x-ray department. This cost will be based on whatever of the following items are provided by the hospital:

1. Space and janitorial service.
2. Heat, light, power, water, and telephone.
3. Laundry and linen supplies.
4. Interest on capital investment in equipment and furnishings.
5. Obsolescence on equipment and furnishings (which fund repays initial investment and covers replacements).
6. Supplies—tubes, screens, films, chemicals, stationery, etc.
7. Repairs.
8. Salaries of such lay help as the hospital provides.

Arrangement 1. Dr. A pays the hospital each month the amount determined as above.

Arrangement 2. The amount determined as above may be divided by the average number of treatments and examinations, and the cost per examination and per treatment determined. Dr. A pays the hospital that amount for each examination or treatment whether he collects from the patient or not.

Dr. B refers his patient to Dr. A (the radiologist) for an ex-ray examination or treatment. Dr. A performs the examination or treatment and renders a bill to the patient on his personal billhead. The patient may or may not pay. Regardless of that fact, Dr. A reimburses the hospital on the basis of either the first or second arrangement, above.

COMMENT

Is it possible to attain such an objective? The report of the Judicial Council of the American Medical Association to the 1936 House of Delegates of that body, which report was approved and adopted, contained the following:

It would seem that in this time of extensive changes in hospital economics the point had arrived at which further marriages between hospitals and staff physicians that make the doctor of medicine the servant of the hospital should be stopped and a series of attempts at divorce among the marriages that have already taken place should be instituted. Our accepted ethical principles are adequate at the present time. . . .

The same House of Delegates adopted the following paragraph in the report of the Reference Committee on Reports of Officers:

Your committee considers that the invasion by hospitals of the field of the practice of medicine should be condemned as a violation of the fundamental rights of physicians, and that it demands militant opposition, to the end that such activities cease.

From the hospital side we have the following statements from the president of the Catholic Hospital Association of America, Rev. Alphonse Schwitalla, as published in the May issue of *Hospital Progress*:

The annual meeting of the American Medical Association cannot but have, each year, the deepest possible significance for our hospitals. As the medical profession thinks, so hospital policies must be shaped or modified. . . . The physician felt in many localities the careless domination of lay groups, who could not possibly bring a professional attitude to bear upon medical problems. . . .

The maintenance of proper relationships between the hospitals and staffs is a fundamental issue. We cannot, therefore, but be convinced that when the House of Delegates of the American Medical Association "took a stand against hospitals which may wink at unethical practices or engage in them, "it was serving not only the medical profession, but also the finest ideals of hospital practice. We join in the sense of triumph which pervades the medical groups of the country. They have won a battle in which the issues were so basic that a redefinition of medical practice would have been imminent if the guide of warfare had turned in a different direction.

IN CONCLUSION

The legal and ethical principles established above are equally applicable to the other medical specialties when practiced in hospitals.

490 Post Street, San Francisco.

DEATHS AMONG FOREIGN RACES IN CALIFORNIA DECLINE*

A study of mortality in California, by races, for the period 1926 to 1935, reveals the fact that deaths of members of the white race have increased more than 2½ per cent during the ten-year period. Deaths among negroes during this time have increased slightly. Indian deaths have remained stationary, and noticeable decreases have occurred in the percentages of deaths among Chinese, Japanese, Mexicans, and members of other races.

MORTALITY AMONG WHITES

In 1926 there were 50,578 deaths in California of members of the white race, and in 1935 there were 64,325 such deaths recorded in California. The percentage of the total increased from 86.1 in 1926 to 88.73 per cent in 1935. The numbers of deaths and the percentages for each year follow:

Year	Total White Deaths	Per Cent of Total
1926	50,578	86.10
1927	52,951	86.20
1928	56,431	85.18
1929	55,939	85.59
1930	56,457	85.31
1931	58,592	86.79
1932	59,205	87.55
1933	59,803	87.96
1934	60,051	88.19
1935	64,325	88.73

NEGRO DEATHS

In 1926 there were 1,130 negro deaths, 1.92 per cent of the total registered in California. In 1935 there were 1,499 such deaths, 2.07 per cent of the total.

Year	Total Negro Deaths	Per Cent
1926	1,130	1.92
1927	1,098	1.79
1928	1,233	1.86
1929	1,211	1.85
1930	1,174	1.77
1931	1,245	1.84
1932	1,310	1.94
1933	1,367	2.01
1934	1,390	2.04
1935	1,499	2.07

* From the *Bulletin*, California Department of Public Health.

INDIAN DEATHS

While there were 283 Indian deaths registered in 1926 and 344 such events registered in 1935, the percentage of the total is practically the same for each year.

Year	Total Indian Deaths	Per Cent
1926	283	.48
1927	267	.44
1928	346	.52
1929	368	.56
1930	418	.63
1931	308	.46
1932	334	.49
1933	314	.46
1934	320	.47
1935	344	.47

CHINESE DEATHS

Chinese deaths dropped from 710 in 1926 to 539 in 1935. The percentage of the total fell from 1.21 in 1926 to 0.74 in 1935.

Year	Total Chinese Deaths	Per Cent
1926	710	1.21
1927	715	1.16
1928	725	1.09
1929	707	1.08
1930	641	.97
1931	611	.91
1932	633	.94
1933	590	.87
1934	525	.77
1935	539	.74

JAPANESE DEATHS

The number of Japanese deaths in California dropped from 814 deaths in 1926 to 683 in 1935. The percentage fell from 1.39 in 1926 to 0.94 in 1935.

Year	Total Japanese Deaths	Per Cent
1926	814	1.39
1927	787	1.28
1928	808	1.22
1929	769	1.18
1930	771	1.17
1931	732	1.08
1932	696	1.03
1933	693	1.02
1934	662	.97
1935	683	.94

MEXICAN DEATHS

There were 5,121 Mexican deaths registered in 1926, 8.72 per cent of the total. In 1928 there were 6,362 such deaths, or 9.61 per cent of the total registered in California. Deaths among Mexicans fell in 1935 to 4,659, or 6.43 per cent of the total.

Year	Total Mexican Deaths	Per Cent
1926	5,121	8.72
1927	5,524	8.99
1928	6,362	9.61
1929	5,943	9.09
1930	6,306	9.53
1931	5,570	8.25
1932	5,014	7.41
1933	4,779	7.03
1934	4,725	6.94
1935	4,659	6.43

DEATHS AMONG OTHER RACES

Year	Total Deaths	Per Cent
1926	106	.18
1927	88	.14
1928	344	.52
1929	426	.65
1930	411	.62
1931	455	.67
1932	430	.64
1933	446	.65
1934	418	.62
1935	451	.62

This study of mortality indicates reduced populations among the Chinese, Japanese, and Mexican races in California. The enforcement of immigration laws affects the Oriental population within the State, and the reduced Mexican population, since 1930, is indicated with marked effect in the reduced numbers of deaths. It is presumed that the increased proportion of deaths among members of the white race is due, in part at least, to the heavy migration of white laborers from other states where particularly unfavorable economic conditions have prevailed.

MEDICINE'S INTEREST IN THE NEXT CALIFORNIA LEGISLATURE*

By PHILIP KING BROWN, M.D.
San Francisco

The frontier must always be the place of trail blazing, and all the United States is interested in the working out legally of a plan for better distribution of medical care in California.

We of the medical profession agree that we know a better plan is needed, but we should like to work it out ourselves. Our leaders have said: "(1) Medicine is, in effect, society's trustee in matters of disease and injury. (2) Medicine accepts this responsibility with the realization that, in the last analysis, the food of society must be the sole aim of its public policies. (3) Medicine's first practical responsibility is to see that, as far as lies within its power, its services are available to all men."¹ "The medical profession is fully conscious of the needs of the sick and the poor, and that great white-collar class who need our help so badly, and will, through our Association, have a way to care for them worked out."² But in the end we have agreed upon no plan and have accomplished precisely nothing. In the meantime a lot of glorified collection agency plans have been put forth, not one of which in this state, or elsewhere, have offered any real solution to the problem of hospital support or adequate medical care on a basis of reasonable profit to its doctor, and anything like complete service to the small wage-earner.³

In the meantime two great national agencies of citizens have taken up the problem and demand action, and some three thousand industries in the country have taken the initiative in developing some sort of medical care for their employees.⁴

TWENTIETH CENTURY FUND

The first of the national agencies to interest itself in the subject is the Twentieth Century Fund and its three thousand credit unions, representing some two million people. Perhaps no single movement has done so much to keep the resources of the masses fluid and usable as this credit union plan of E. A. Filene, organized under common employers, buying their own stock and lending to each other at times of emergency or unusual strain. Such credit unions as the school teachers' in New York City have capital of several millions, and lend at a low rate. While 6,900 banks have failed during the depression, no credit union has failed. Another brilliant idea of Mr. Filene has been a study of what members borrowed for, and it developed that 22 per cent was to cover the expense of unexpected illness. So Mr. Filene has done two more memorable things: to have exempted legally from attachments a certain amount of a man's holdings in his credit union, and secure federal support for the plan. In every state in the Union there are federal agents, as well as the employers of the unions, engaged in promoting the movement.

Mr. Filene and his Twentieth Century Fund have been giving a great deal of study as to how these two million members can buy medical care on a safer, surer and more reasonable basis.

FARM BUREAU ORGANIZATIONS

The next great national movement has originated in the Farm Bureau organizations, chiefly here in California. A study of what San Joaquin County has done through its county hospital has convinced farmers' wives that the opening of county hospitals to citizens generally was the answer. Thirty of California's fifty-eight counties have hospitals that accept paying patients under different conditions.

It is the purpose of this brief article to point out the dangers, difficulties, and wholly inadequate service which would accrue to the public if either of these plans were carried out.

*An address delivered at the National Farm Bureau convention December 8, 1936, in Pasadena.

³ The reader is recommended to study the Alameda plan in this State and the Wayne County plan in Detroit.

⁴ Details in the forthcoming volume by Elizabeth Marshall of New York.

EXPERIENCE OF THE CREDIT UNIONS

First, the credit union forces, having found out that nearly one-quarter of the money borrowed from the unions by their members was for medical care, sought to devise plans for procuring it on more practical terms than were offered by private practice or charity. Mr. Evans Clark, secretary of the Twentieth Century Fund, has published a volume on Budgeting for Health, and in it he has expounded very ably all of the methods that have been devised for lessening the costs of medical care to the small wage-earner. His criticisms of these plans are good. More than that, Mr. Filene himself gave the first \$5,000, which started seriously the Committee on the Costs of Medical Care. Both the profession and the laymen might easily feel that in such apparently understanding hands their several causes were safe, but somehow these able leaders were not good enough historians.

The age-old cause of lodge practice has seemed to appeal to the older credit unions in the East. They wish to accomplish what the medical profession regards as two utterly disastrous ends: the right of each union to hire doctors on salary, and the right of corporations to practice medicine. For sixty years, all over the United States, both of these principles have been fought vigorously by the organized profession, and the courts everywhere have sustained the rule that corporations may not practice medicine. Lodge practice has been an effort to buy medical care cheaply. All lodges have used their cheap medical service as an advertising influence, and the best of them pay \$100 to \$125 a month and hire one doctor for each one thousand members. Members are treated free; small fees are asked of dependents. Certain services are charged extra. The cost averages \$2 a month. Some of the lodges send 85 per cent of this East for certain causes which they support. Others spend goodly sums on orphan asylums, old people's homes, care of their tuberculous, and hopelessly ill. Emphasis is put chiefly on the benefit which appeals most in some particular neighborhood. There is no uniformity in policy. A few good doctors have undoubtedly done lodge work for a starter, some have undertaken it for political reasons, and a few try seriously to carry out their obligations. Some country towns without doctors have devised no better way of getting one to settle in their midst than to establish and develop some sort of a lodge, and then look about for the cheapest doctor they can find. It should be obvious that with the growth of the science of medicine and the need for some specialization, this sort of practice promises little. Most lodge doctors have endured but briefly if they have had any ambition or ability. It is only fair to say that the western credit unions which have sought to act individually have made a good many studies of how medical service might be procured at a price more reasonable than possible at present, and have been brought to see that most states will require some additional legislation before anything can be done, and then they look forward to asking the organized profession to give them its best plan. It is quite possible that our next legislature will pass some enabling act putting all health insurance efforts under the Insurance Commissioner and some board like the State Board of Health, in order that all such plans may be sound financially and medically before they go into operation.

STUDIES OF THE FARM BUREAU ORGANIZATIONS OF CALIFORNIA: COUNTY HOSPITALS

The second mass action was proposed by the Home Economics Department of the Farm Bureau Organizations throughout California, who have circulated petitions to all of their members and as many others as they can interest, hoping to get action from local boards of supervisors, who will make demands upon the counties to the end that the county hospitals may be opened to anyone. The latter part of the ordinance which they are supporting reads as follows:

"And pursuant to Part IV, Title II, Section 4003, of the Political Code, 1 to 5 inclusive, and Section 4223 of the Political Code, the Board of Supervisors of the county of _____ do hereby ordain, under the mandate of the people, that the county of _____ shall operate the county hospital and out-patient medical services for the welfare of the people of the county; that the part of the tax dollar which maintains the hospital and the out-

patient medical service shall be the yearly insurance of the people that the hospital and medical service will be available when and if they need it at the daily cost of the service, and the hospital shall not be operated on a tax levy for care of indigents. For those unable to pay in full for the service, they shall pay any part of the cost which they are able to pay.

"Those incapacitated by age, disease, or accident, not able to pay any part of the cost, shall be cared for free, on the same standard of service as those who pay.

"The Board of Supervisors of the county of _____ do further ordain that there shall be no stigma of pauperism attached to the hospital service provided by the county, and that such service shall be regarded, supported, and utilized in the same democratic spirit which prevails with relation to any other public service operated, supported, and maintained by public funds."

The whole issue of the county hospital is one that needs revision, and there are a few states, and one municipality particularly, that have solved the problem satisfactorily. Michigan extends the open door of its county hospitals to the doctors of the state, and the large county hospital of Buffalo, New York, does the same. Patients are encouraged to have their doctors attend them, and every effort is made by the public authorities to keep as many as possible of the people who are handled in the county hospitals under the medical care of their own physicians. What they pay these physicians is a matter entirely between doctor and patient. If they can pay a small sum for hospital care, they are charged it.

The trouble in California is that the county hospital in many counties is either the only one or is the best one. Los Angeles has spent between fifteen and twenty million dollars on its county hospital, and it is not surprising that the small wage-earner looks with some bitterness on the fact that out of whatever taxes he pays, part goes to support a hospital to which he has no access.⁵ The social service rule of the Los Angeles General Hospital states that if the family earnings are more than \$60 a month no member of a family of four may enter the hospital. If the earnings are \$60 a month or under, they are welcome. It is the feeling of the writer that every intelligent physician in the community will agree that out of the \$61 a month for even one person there is nothing to be saved to provide medical care for any illness. The Social Welfare Department of the State, which has some supervisory relation to this hospital, has no real control over it. Its authority is limited "to investigate and examine and make reports to the legislature on the conduct of institutions operated for the care of indigents." It is held by some counties that they are privileged to operate hospitals in which charges are made for certain patients, and they point to Section 4223 of the Political Code to justify their position. The claim is made, for example, by the San Joaquin General Hospital that Los Angeles, San Francisco, and Kern County operate under the pauper provision of Section 1. Section 4041.16 of the Political Code. The crux of the situation, however, lies in what was pointed out in a letter to Mrs. Turner of the Department of Social Welfare of Sacramento in which the legal department of the Attorney-General's office, in defining the term "county hospital," as used in the Kern County Hospital case, states that the legislature has never defined a county hospital, but that the decision of the court in the case of *Goodall vs. Brite* directed in its decree to the county and those officials in charge at the hospital "who should be admitted to its county hospital." The decision makes extremely plain that "no people of the class of persons described in paragraph 3 of the rules may be admitted to said hospital except in cases of emergency." Paragraph 3 authorizes the admission of persons unable to pay for and obtain proper and necessary medical, surgical or hospital care for themselves elsewhere than in the county hospital, deeming such persons obviously dependents, and leaving it to an admission board as to what proportion of the cost of hospitalization they are able to pay. As there are some thirty hospitals among our county hospitals who receive patients who pay something, this decision if maintained puts them all in the position of acting irregularly. It would be necessary for an act of the State

Legislature to be passed to open county hospitals to the public generally. This decision is quite the reverse of an opinion of the Attorney-General written to the District Attorney of Sonoma County November 7, 1934, in which it was argued that certain patients who could pay something should do so. The Attorney-General quoted the rule about our state insane asylums which requires payment from those who can afford it. There is another aspect of the county hospital question which needs to be pointed out. The Social Welfare Committee has divided these hospitals into five groups, of which only the first, containing sixteen hospitals, is accepted as class "A" by the American College of Surgeons. The one thing about all of them, which is absolutely wrong, is that they have volunteer staffs. The writer believes that this is not wholly true, because the San Joaquin Hospital is mentioned among those sixteen, and all of its doctors are paid something, although most of them get merely \$100 a month for what they do. The other four groups vary from a fair medical and surgical service, lacking one or more essentials, to boarding houses operated by a man and his wife in old wooden shacks where the county physician is telephoned to, to come and see anyone who seems to be sick enough to require some attention.

It would require \$50,000,000 to buy land and equip decent county hospitals for those counties that lack them in this state, and then the charge per day would have to be in the neighborhood of \$6 even in wards. The supervisors should take cognizance of the criticisms of the \$3 rate by the Fourth Appellate Court, Civil No. 1761, January 30, 1936: "The method used in reaching the daily cost per patient was so inaccurate and unbusinesslike that the result would not reflect the true daily cost to the county." Property taxes, depreciation, insurance, and interest charges on the investment in land and building, all should be made part of the cost.

There seems to be one answer to this entire situation. The great indigent and small wage-earning class of the community will have to be supported in sickness by taxation, insurance, or a combination of both. Given a compulsory health insurance law, and absolutely class "A" county hospitals like those, for example, in Los Angeles, San Joaquin, and San Mateo, all of the small wage-earners who entered such hospitals would have their bills paid from the insurance fund; the county would have to (as now) pay for the care of its dependents. The one other big change which the organized medical profession should fight for is that first-class county hospitals should be opened to every licensed doctor, so that he might follow his patient requiring hospitalization until his discharge. It works wherever it has been tried, and it would seem to be in the interest of both the medical profession and the public.

909 Hyde Street.

THE CONFERENCE ON SYPHILIS*

More than five hundred persons responded to the call of Surgeon-General Thomas Parran of the United States Public Health Service for a three-day conference in Washington recently on the control of venereal diseases, especially syphilis. Representatives of the American Medical Association, officers of state medical societies, and practicing physicians attended, as well as health officers and social service workers. The conference was asked to consider the question of venereal disease control from six principal points of view. The reports that were adopted by the conference as a whole on the third day were in substance as follows:

1. Estimates were presented of the prevalence of syphilis in the United States. A minimum of 681,000 new cases of syphilis was declared to be the probable annual incidence of the disease. Prevalence in the population as a whole was estimated variously at from 5 to 10 per cent of the population, including syphilis in all its stages from initial infection to the late sequelae. . . .

2. The section on the public health control of syphilis stressed the necessity for carrying treatment facilities to all persons of all economic strata. Emphasis was placed, however, on the fact that no desire existed on the part of

⁵ See "The Care of Dependents," a publication by the Los Angeles Budget and Research Department, p. 90, 1936.

* Excerpts from editorials published in *The Journal of the American Medical Association* for January 9, 1937.

the public health officials to undertake the treatment of all cases of syphilis at public expense. It was declared that whenever and wherever possible patients should be treated by family physicians in the usual manner and that the personal relationship of patient to physician should be maintained wherever possible. The section reported that in its judgment the treatment of indigent and borderline patients in clinics would be a necessity. Adequate social service for the clinic to ascertain the degree of ability to pay was dealt with in another section. Reporting of the venereal diseases was stressed as a necessity in their control. The section recommended that the Surgeon-General request reporting by name and address as in the case of other communicable diseases. This recommendation of the section was opposed from the floor of the conference and ultimately was amended to read, in effect, that reporting by name and address be encouraged where practicable, but that in other localities reports by number or by initials and date of birth be accepted for the present in order to allow opportunity for overcoming the well-known reluctance of physicians to report venereal diseases by name. The necessity for furnishing laboratory service gratis and for the free distribution of drugs needed in the treatment of venereal diseases through public health authorities was stressed. A recommendation to the effect that prophylaxis be regarded as an integral part of the syphilis program was opposed from the floor. The opposition, however, was overwhelmingly defeated and the report of the section, therefore, included the recommendation that prophylaxis be included in the antisiphilic program.

3. The section on treatment presented a voluminous report, of which the salient points were the importance of early treatment and the treatment of the pregnant syphilitic woman. Emphasis was laid on the necessity for continuous treatment except in the case of late syphilis in persons of middle age or beyond; on the importance of confining the distribution of drugs through public health departments to established preparations, namely, the arsenicals, bismuth compounds, mercury ointments, and possibly iodid preparations.

4. The section on medical follow-up of the venereal disease patient reported the importance and necessity for follow-up in certain types of cases. Much follow-up work can be prevented by efficient, courteous, and expeditious handling of patients on their first visit to the clinic. . . .

5. The section on coöperation of the private physician in the control of venereal diseases made a report which indicated the dual responsibility of the physician in any case of communicable disease, including the venereal diseases. This responsibility is for the patient and for the community. . . .

The principles here presented seemed in general to meet with the approval of all groups represented. Recognition was given to the fact that conditions in the United States differ widely in different localities and even sometimes within a single community, and that programs, subject only to general fundamentals, must be varied and adapted to meet local needs. . . .

In all probability most indigent patients in denser population centers will need to be treated in clinics. In smaller communities and rural areas, treatment of the indigent was recommended through the offices of family physicians. The recommendations included payment of the physician on such a basis as might locally be agreed on for services rendered to indigent patients. Certain questions were raised relating to the lack of uniformity of instruction in syphilology in the medical schools. . . .

CALIFORNIA STATE BAR CHASES AMBULANCE CHASERS*

The State Bar of California has a committee, known as Special Local Administrative Committee No. 1, whose duty is to investigate and institute prosecutions of ambulance chasers, both lay and attorney. The personnel of this committee is John E. Biby (chairman), John M. Bowen, and Robert M. Clarke; staff, Philbrick McCoy, counsel, and Herbert Hallner, special investigator.

The above-named committee has been successful in securing convictions and pleas of guilty in more than fifty cases. Many of the offenders have received jail sentences

of 180 days and fines in the amount of \$500. Among those convicted was a member of the medical profession.

Of interest to the medical profession is the fact that this committee has in several instances secured information to the effect that certain physicians are very active in the solicitation of business for certain attorney ambulance chasers. This condition appears quite aggravated among some of the physicians who conduct private emergency hospitals. One such offered medical treatment and hospitalization to an injured person if he would employ a certain attorney to prosecute his claim for damages, the cost thereof to be paid only out of any money recovered!

This State Bar committee frequently finds it difficult to prove the facts necessary to secure a conviction in these cases. Its investigations disclose that the attorney involved has received a written or telephone request from the injured person to call on him; and, when questioned, the attorney invariably says he did not know the request was instigated by the physician. The physician often excuses his conduct by stating that the injured person requested him to recommend an attorney.

The State Bar deserves commendation for the work it is doing to eliminate the evils arising out of ambulance chasing. Any member of the medical profession acquiring knowledge that a physician is in any manner aiding an ambulance chaser should report at once to any member of the State Bar committee or its staff, or to The State Bar, 440 Rowan Building, Los Angeles (Los Angeles telephone, Michigan 9551). Such coöperation with the State Bar will do much to purge both professions of the odium cast upon them by members who are aiding or coöperating as ambulance chasers.

HEALTH INSURANCE PROPAGANDA*

On Monday, November 23, 1936, a newspaper of the city, the *New York Herald-Tribune*, gave its columns over to a piece of propaganda which deserves attention. Under date of November 22, 1936, and presumably coming from Washington, a feature article is written, headed "Health Insurance Study Is Instituted by Security Board."

Like all propaganda, the "news-spread" necessarily must be tacked to some event, and so this time we find it tacked to some casual recommendations made by Harry Hopkins, WPA Administrator, in a speech to the United States Conference of Mayors recently; and, incidentally, it is also tacked to a report of the Executive Council of the American Federation of Labor. Then, not giving either the speech made by Mr. Hopkins or the substance of the report of the Executive Counsel of the American Federation of Labor, the propagandist in question hides his identity under the statement, "A spokesman for the Social Security Board." For the rest of a column and a half of ordinary newspaper space there is nothing but argument and propaganda, and little or no factual news. In the end the reader is left to wonder *who* is advocating health insurance, who is putting forth the arguments for it, who says that it is to be considered purely as a tax measure, and who is it that is forcing attention to it and arousing argument.

The stress presented in the newspaper broadcast consists primarily in the fact that existing systems of unemployment compensation and old-age benefits "are generally believed in Security Board circles as measures to bring health insurance to the fore" and "almost all European countries have comprehensive plans of health insurance providing cash benefits in disability and invalidity and supplying medical aid." The plea ends with the statement that it can be conducted on a pay-as-you-go plan.

In the September 1 issue of the *New York State Journal of Medicine*, editorial note was made of the "lull before the storm." An ominous silence was noticed on the part of the protagonists for health insurance. We were then aware that the protagonists of health insurance had not quit. We rather resent the fact, however, that *government agencies* should engage in propaganda to create a demand for something which the public has neither asked for nor needs.

The news release also announces that more time to study the proposition is asked. We seriously recommend that it be studied; that comparison be made of the morbid-

* By J. E. B.

* Editorial from *The New York Medical Week*, November 28, 1936.

ity and mortality statistics abroad with those here; that the uses which are made of preventive medicine abroad with that here be taken into account. We could go on at length, but of what avail to argue with those whose minds are made up. What can one expect from Walton Hale Hamilton, the economist head of the research division, a former member of the National Industrial Recovery Board! We know him through a different activity. He was one of those who, under Ray Lyman Wilbur, brought out the report of the Committee on the Costs of Medical Care which recommended health insurance; and he wrote his own special report on this thesis, which in itself was but an elucidation of the preconceived object of the committee, from the pen of its director, Henry H. Moore.

President Roosevelt has announced that there will be no measures proposed calling for the necessity of adding to our present heavy tax burden. Furthermore, the President, in his address in Jersey City, gave the profession assurances that it would be consulted and its wishes given attention when changes affecting medical practice came under consideration. Our conception of consultation and consideration does not envisage government spokesmen speaking for their preconceived ideas, long fixed, of how medical practice shall be arranged.

It has been jocularly said that the many governmental functionaries who speak publicly for the administration have so managed things that the Washington Administration can take more sides on any given question than is possible of geometrical demonstration. In this question of medical care, at least, let us have plain, straight thinking and speaking. There should be but one side to the problem. How to provide the highest possible *quality* of medical care to those of the public that need it, and to make provision that financial barriers shall not stop those needing it from getting it.

GUARDING THE SIGHT OF SCHOOL CHILDREN

The years of school life are usually the period of greatest stress and danger for eyesight, declared Dr. Edward Jackson of Denver, Colorado, at the annual conference of the National Society for the Prevention of Blindness, in Columbus, Ohio, recently. Doctor Jackson is Emeritus Professor of Ophthalmology at the University of Colorado. Speaking on "Guarding the Sight of School Children," he said:

"The prevention of blindness implies the conservation of partial sight, and is only complete when it is applied early in life. For the majority of people, the years of school life constitute the period of greatest stress and danger to their eyes.

"Accidents are responsible for 16 per cent of the causes of complete blindness, and more than half of these accidents occur to boys and girls under twenty.

"Prevention of disease has of late years been very widely applied, and results have far surpassed those of medicine and surgery in treating disease. Smallpox caused one-eighth of the blindness in the civilized world before vaccination was introduced, and still causes many cases of blindness where it is not practiced. But this proportion of blindness has been completely prevented by vaccination.

"Oliver Wendell Holmes, professor of anatomy, said that it was necessary to go back three generations to prevent some forms of disease. Many have approved of the statement, but we have not yet begun to apply prevention to one whole generation. Care of the eyes during school life is an attempt to make such an application to the prevention of blindness.

"In the school, we have light that is very inferior to the light of outdoor living. The sun at different times of the day gives light of 1,000 to 10,000 foot candles. In schoolrooms we rarely find light about 100 foot candles on the desk of the students, and sometimes it runs down to ten or five—or even two or one—and the children's eyes are expected to stand their school work under such bad conditions.

"Anyone can judge the effect of poor light by taking a telephone directory, which always has small print in it, and looking at it first in an ordinary indoor light, and then holding it where the sun will shine upon it. No one can miss the lesson of greater ease in using powerful light.

"When people think the light is too bright, it is usually because they have been trying to look at it. Our sources of light are not generally to be used like Neon signs, but to illuminate the desks or studies which we are trying to carry on. In the schoolrooms, many errors are tolerated with reference to the lighting; teachers and pupils need to be instructed in how to give their eyes the best chance by appropriate arrangement of the light.

"The correction of optical defects of the eye has been widely stressed and deserves all of the emphasis that has been placed upon it; but even with the optical defects exactly corrected, care and moderation need to be used for even the best eyes.

"The common causes of blindness that come with old age, like cataract and glaucoma, or hardening of the eyeball, have generally been threatening or actually progressing for years before they cause blindness. In a person of sixty-five with beginning senile cataract, it is probable that it will be fifteen years before he is unable to read and probably twenty years before he has to have the cataract removed. This time allows abundant opportunity for preventing the diseases that destroy sight in old age."

A PERTINENT QUESTION

Is it common sense to let a healthy, young mother die in childbirth at the very beginning of her productive and creative years because of *ignorance and negligence*? Motherhood is a question facing not only expectant mothers and fathers, but the community at large. Each community must recognize its responsibility in the education of its young people for the responsibilities of parenthood, so that they may know how and when and where to seek and secure adequate medical and nursing care when a baby is on the way.

What should young people know to prepare them for parenthood? There are ten simple facts which should be included in the education of every young person. Each should know that:

1. A baby lives for nine months in its mother's body before it is born.
2. An expectant mother should seek the advice of a competent doctor as soon as she *thinks* a baby is coming.
3. Throughout pregnancy the doctor should be consulted regularly so that he may be on guard for the first suggestion of beginning abnormalities.
4. When in doubt, the doctor's advice should be secured; it is better than that of friends or relatives or neighbors.
5. The mother's daily routine should be based on common-sense living—no burning the candle at both ends.
6. The responsibility for having a baby is as much the father's as the mother's; he should help his wife follow the doctor's instructions, boost her spirits when she is down, and relieve her of worry and fatiguing physical work.
7. If the baby is to be born in a hospital, a good one should be selected; approval by the American Medical Association Council on Hospitals or the American College of Surgeons is the hallmark of a good institution.
8. If the baby is to be born at home, preparations should be made in advance under the direction of the doctor or nurse.
9. The mother should remain in bed at least ten days after the baby's arrival, and should do her first mothercraft under supervision.
10. A detailed plan should be made for the baby's care before it arrives so that things will run smoothly from the very beginning.

All parents should see that their children, as they grow to maturity, know thoroughly these basic facts. If they shirk their responsibility, they are missing one of the greatest challenges which comes to a parent. It is also the responsibility of various community organizations to help train young people for parenthood. The school should endeavor to help each pupil develop a wholesome attitude toward the facts of life; the church a high moral code; the settlement houses, Boy Scouts, Girl Scouts and similar organizations a strong, sturdy character. If these important units in our society shoulder fully their responsibilities in preparing young people for parenthood, we shall find not only a reduction in our maternal deaths, but also an improvement in marital relations.

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. X, No. 2, February, 1912

Special Notice:

Forty-second annual meeting of the Medical Society of the State of California.

Del Monte Hotel, Del Monte, April 16, 17, and 18, 1912.

Railroad rates the same as usual; one and one-third fare for the round trip. . . .

From Some Editorial Notes:

Owen Bill.—A number of requests for a copy of the last Owen bill to create a Department of Public Health have been received, and as the matter is of the greatest importance to public health, the *Journal*, elsewhere in this issue, prints the bill in full. It will probably be some time before the Congress will enact any law of this nature, and it is quite possible that when such a law is finally passed it will differ somewhat from the present proposed measure. . . .

Exploiters of Nostrums.—A good many of the most prominent physicians and surgeons in this country are helping to exploit and promote the use of some unspeakably noisome nostrums. Some of the "leaders of the profession"; some of those we are all in the habit of looking up to; some of the leaders in the American Medical Association, are doing just this, though they may not realize it. How? By contributing articles to so-called medical (?) or surgical (?) journals that accept the advertisement of these rotten things. . . .

Medical Defense.—Though the coöperative plan of defending our members in all actions for alleged malpractice has been in successful operation since July 1, 1909, and although, parenthetically, *no judgment has been entered against any practitioner in this State since that time*, a number of our members do not seem to understand it. For this reason, and for the reason that certain insurance companies have seen fit to make untrue remarks, it seems wise to set forth, in full, the general plan and scope of the work, rules, etc. The plan itself is the simplest form of coöperation; the members of the Society have decided that, through the machinery of the State Society, they will defend each other in all actions for malpractice that may be brought against members. To cover the cost, a small amount was added to the annual assessment, and it has been found to be ample. The rules laid down by the Council and prepared by our attorney, and subsequently approved by the House of Delegates, are about as simple as any rules could be.

First: All communications must be made to the Secretary of the State Society, Butler Building, San Francisco, California. This is in order to avoid confusion or doubt and concentrate all correspondence in one office.

Second: If a suit is threatened, do not wait for it to be filed, but notify the secretary immediately. The matter is then placed in the hands of our attorney and, as a rule, no suit is brought.

Third: Be sure that you are at all times in good standing (dues fully paid up) in your county society. Only members in good standing in a county society (and therefore in good standing in the State Society) will be defended.

Fourth: The alleged malpractice must have occurred after the first day of July, 1909, and at some time when the defendant was a member in good standing in his

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By CHARLES B. PINKHAM, M.D.
Secretary-Treasurer

Board Proceedings

The following citations have been issued returnable at the next regular meeting of the Board of Medical Examiners, to be held at Independent Foresters Hall, Los Angeles, commencing February 8, 1937:

Edward H. Anthony, alleged narcotic dereliction.
Robert V. Baker, violation of probation.
James H. Beggs, conviction, Pacific Coast Abortion Ring.
Samuel D. Burgeson, Jr., alleged narcotic dereliction.
Frank T. Cary, violation of Harrison Narcotic Act.
S. N. Chernyh, alleged narcotic dereliction.
John E. Cummings, continued from October meeting.
Merton E. Eastman, aiding and abetting unlicensed practitioner.
Thomas Flint, Jr., narcotic addiction.
Henry L. Gardner, continued from October meeting.
James Harvey Johnston, narcotic conviction.
Oscar Charles Long, violation of Harrison Narcotic Act.
Samuel C. Long, alleged illegal operation.
Thomas S. Long, use of fictitious name.
L. J. Otis, alleged narcotic dereliction.
Allen H. Peek, alleged narcotic dereliction.
Jesse C. Ross, conviction, Pacific Coast Abortion Ring.
Alfred H. V. St. John, conviction, Pacific Coast Abortion Ring.
Leo M. Schulman, alleged narcotic dereliction.
Francis W. Steddom, alleged narcotic dereliction.
William D. Teepell, fictitious name.
George E. Watts, conviction, Pacific Coast Abortion Ring.
Henry C. Wallace, narcotic violation.
C. B. Wiley, commitment.
Glen G. White, alleged illegal operation.
Edgar H. Williams, alleged narcotic dereliction.
Thomas D. Wyatt, continued from October meeting.

News

"California doctors apparently are not interested in \$200 a month positions with the State. The Personnel Board found it necessary to postpone two examinations for Civil Service positions because an insufficient number of doctors applied. One position, that of Assistant Medical Director of the State Industrial Accident Commission, is located in San Francisco, and pays \$200 per month for part-time work. The other position, as Assistant Surgeon in the Veterans' Home at Yountville, pays \$200 per month plus maintenance for the surgeon and his family." (United Press dispatch, dated Sacramento, December 28, and printed in the *San Francisco News* December 28, 1936.)

Recent inquiry came from Louisiana regarding an individual named S. H. Staples, who falsely claims to be a graduate of the University of California Medical School and to be licensed under the Medical Practice Act of California. Just another impostor!

"Roy L. Martin, fake eye doctor, who in April, 1931, fleeced Dan Carey of this county out of \$500 on a promise of a cure of eye trouble, has been arrested in Los Angeles County, but so many charges are awaiting him that it is doubtful if he will be returned here for trial. He will likely face federal charges of using the mails to defraud. Orange, Stanislaus, Riverside, and Sacramento counties are among other counties having charges against Martin. His arrest came as the result of a circular issued by

BAXTER'S ARE THE PIONEER SOLUTIONS

IF YOU will but turn that over in your mind, there will come a recognition of the reasons why Baxter's are so famous. Baxter was the pioneer. Baxter's straddled its job and rode it hard. . . . Made its name world famed, because it gave to physicians perfect solutions . . . solutions as correct and as uniform and as fine as they would have made them themselves had they the time and the surety and Baxter's modern laboratories. Baxter's was first and Baxter's have always been first in all things pertaining to intravenous therapy. Baxter's, the pioneer, are perfect solutions in perfect dispensing containers.

Courts Back Up Food and Drug Administration.—Federal courts throughout the country assessed higher penalties during November than the average of the past several years, the monthly report of the Food and Drug Administration indicates. . . .

Several terminations were entered in drug cases. Lee Kelpodine Co., Inc., John Lee Clarke, and William J. A. Bailey, all of New York, "Kelpodine Tablets," consisting of compressed kelp (a seaweed), fraudulently offered for the treatment of pyorrhea, headache, indigestion, tuberculosis, cancer of the liver, glandular trouble, nervousness, dental caries, underweight, anemia, constipation, general weakness, melancholia, digestive disturbances, asthma, rickets, bone diseases, chlorosis, eczema, stomach disorders, nervous breakdown, migraine, high blood pressure, stomach ulcers, hay fever, liver congestion, subnormal growth, mental exhaustion, neurasthenia, rheumatism, arthritis, obesity, and other conditions for which the product was not a competent treatment, fine of \$100 against the company and against each individual (\$300 in all) Lee Co., Inc., and John Lee Clarke, "Kelement," a similar kelp fraud, fine \$50 each; John Lee Clarke, trading as Seavigor Co., New York, "Seavigor," still another, and similarly misbranded, fine \$200, suspended.

Tested Specialties Co., Chicago, Illinois, "On the Nose," a lard ointment, containing 15 per cent mercury, for colds, coughs, sneezes, sniffles, running nose, watery eyes, fever, loss of pep or appetite, and worms, in dogs, cats, foxes and all fur-bearing animals, was fined \$25.

Standard Chemical Co., and John W. Gamble, Omaha, Nebraska, "Fumoil," consisting of chlorinated lime, oil of eucalyptus and sulfuric acid, for colds, bronchitis, influenza, and pneumonia in poultry and hogs; "Standard Heave Powder," a mixture of calcium carbonate with small amounts of iron and sodium sulphates and phosphates and bitter plant drug, for heaves, distemper, and epizootic in horses; and, "Standard Necro Tabs," containing copper sulphate, potassium permanganate and talc, for necrotic enteritis ("necro") in hogs, were fined \$55 each (total \$110) and costs. Samuel Kovacs and Joseph Weishaus of the Royal Manufacturing Company of Du-

Sleep...

NATURE'S AID IN THERAPY

FREEDOM from mental strain or nervous apprehension is often a factor of vital importance in the favorable outcome of disease or of operative procedure.

Where normal sleep is difficult, the use of hypnotics or sedatives is often indicated.

Ipral Calcium (calcium ethylisopropylbarbiturate) is a safe sedative which induces a sound, restful sleep closely resembling the normal. It is rapidly and readily absorbed, effective in small dosage and rapidly excreted. No untoward organic or systemic effects have been reported from its use and undesirable cumulative effect may be avoided by proper regulation of the dosage.

Ipral Calcium is supplied in 2-gr.

tablets and in powder form for use as a sedative and hypnotic.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 2-gr. tablets and capsules for hypnotic use and in 4-gr. tablets for preanesthetic medication.

Tablets Ipral Aminopyrine (2 gr. Ipral, 2.33 gr. Aminopyrine Squibb) provide both analgesic and sedative effects.

Ipral Calcium (Powder) is available in 1-oz. bottles. Tablets Ipral Calcium, 2 gr., Tablets Ipral Aminopyrine 4.33 gr., Tablets Ipral Sodium, 2 gr. and 4 gr., and Capsules Ipral Sodium 2 gr. are available in bottles of 100 and 1000.

quesne, Chicago, Illinois, "Double D Cod Liver Oil," found not to be twice the vitamin D strength of United States Pharmacopeia cod-liver oil, and bearing extravagant therapeutic claims, fine of \$25 against each partner; Hepatin, Inc., Chicago, Illinois, "Heptuna Capsules with Vitamins A B D G," lacking in vitamin B, fine \$50; and Haarlem Research Laboratories, Inc., New York, N. Y., Superior Pharmacal Company, Dayton, Ohio, and Charles H. Dietz Company, St. Louis, Missouri, substandard pharmaceuticals, fines \$100, \$100, and \$225 and costs, respectively.

Drug products seized included one lot of substandard tincture of aconite, and seventy-two packages of gauze bandage represented as sterile or sterilized, but found on test to be contaminated with living organisms. These patent medicines were also picked up: "Beck's Little Wonder Headache Powders," each powder containing four and one-half grains of acetanilid, with caffeine and potassium citrate, represented as containing no drug of the acetanilid type, offered for sick and nervous headache, toothache, grippe, malarial headache, fever and ague, and falsely represented as "safe"; "Croup Monia Cough Syrup," containing ammonium chlorid, glycerin, alcohol, 1.3 minims chloroform per fluid ounce (the label declared 4 minims per fluid ounce) menthol, and plant extractives including pine, for coughs, hoarseness, bronchial irritations, croup, and whooping cough; "Dunlap's Antiseptic Liniment," 78 per cent alcohol (the label claimed 35 per cent) with water, chloroform, a plant extract, ammonia, oil of sassafras and oil of eucalyptus, for rheumatism, neuralgia, toothache, headache, colic, diarrhea, and cramps; "Dunlap's Colic Remedy," 51 per cent alcohol (35 per cent declared on the label), with water, ether, and small amounts of asafetida and camphor, for colic in horses and mules; "Gay," tablets, each containing two grains acetylsalicylic acid, 1.7 grains acetphenetidin and one-quarter grain caffeine, with plant material, bearing no declaration of the presence of an acetanilid derivative, and falsely represented as containing no harmful drugs and as non-habit-forming, for the relief of pain; "Lee's Creo-Lyptus," a syrup containing ammonium chlorid, alcohol and small amounts of creosote, pine tar and eucalyptol, for persistent coughs, spasmodic croup, bronchial congestion, whooping cough, tuberculosis, chronic bronchitis, pneumonia, and asthma; "Lee's Prescription," capsules, each containing 3.62 grains acetanilid, 3.52 grains acetylsalicylic acid, and caffeine, for lessening the paroxysms of hay fever and rose fever, and for sinus, grippe, running nose, weeping eyes, etc.; "Poochie Worm Remover and Conditioner," a short-weight canned article, consisting of water, oats, meat, hair, charcoal, fish oil and sodium and calcium chlorides and phosphates, represented in its labeling as containing more protein and fat than analysis disclosed, and offered as a conditioner, and for the removal of intestinal worms in dogs and cats; "Sanadon," consisting of water, sugar, guaiacol, hypophosphite, and wintergreen, falsely represented as antiseptic, and offered for the treatment and prevention of infections of the mouth, teeth, and gums, such as pyorrhea, gum ulcerations, bleeding gums, canker sores, stomatitis and sore throat, and for stopping pain, reducing inflammation and relieving soreness and bleeding; "Dr. Mary E. Stewart's Antiseptic Powder," boric acid and zinc sulphate flavored with eucalyptol and wintergreen, not antiseptic as represented, for women's ailments; and "Vacher-Balm," petrolatum with menthol and oil of eucalyptus, for catarrh, spasmodic croup, and pain.

Social Insurance Questions.—Up to now, every worker who has no dependent children and who earns 21,000 francs (about \$1,000, after devaluation of the franc) is obliged to take out social insurance. The employer pays a monthly premium equal to that paid by the worker. A worker who has two or more dependent children and who earns 25,000 francs must be insured. The government has recently proposed a law according to which these salary limits will be raised, so that a large number of workers not now insured will be obliged to join the social insurance organization. In a letter addressed by its president, Doctor Tissier, to the Federation of Medical Syndicates of France, dated August 6 and published in the Sep-

tember issue of the *Bulletin* of the Syndicate of Physicians of the Department of the Seine, the statement is made that, although the question of raising the limit of obligatory insurance is more of an economic than of a professional character, the extension of social insurance, especially in the region of Paris, to a considerably larger number of workers cannot fail to be of interest to the practitioners of this region. The application of the social insurance law has already affected the practice of medicine seriously and imposed a heavy burden, which the profession has accepted in a most loyal manner. Confronted with the proposed modification of the law, the profession feels itself entitled to claim an application of the law which will permit a physician at least to earn a living; hence the authorities are requested to consider the present plight of the profession in France before raising the limit of obligatory insurance. No one can ignore the loss of time, the vexatious examinations, the abusive investigations to which a physician is subjected in connection with the medical control demanded by certain caisses or bureaus which pay the claims for illness of the insured. This is especially true of patients treated by the practitioner at his office or at the home of the insured. These disagreeable encounters between the medical inspectors of the caisses and the practitioners, often taking place in the presence of the patients and tending to cause them to lose confidence in their medical attendant, should in the future be avoided in the case not only of those already insured but also, if the proposed limit is raised, of those in the higher salaried brackets, who are more likely to consult a physician than those in the present lower brackets. The original law of 1930 had given the insured workers and their medical attendants a certain number of guaranties, such as free choice of physicians and the equitable adjustment of indemnities, which has induced the majority of the working class to accept the law. The law as modified in October, 1935, which was not passed on by the legislature, added a number of restrictions, which have increased the power of the caisses or disbursing bureaus. The regional boards on which the organized medical profession is represented are seldom summoned to meet with the superior

council of the social insurance organizations. The secretary of the Federation, in his answer to this letter, stated that most of the abuses to which the local (Seine) organization had directed attention were only in the power of the main social insurance organization and its subsidiaries to correct. As to the higher limit of obligatory insurance, this will not go into effect, as proposed in the recent bill.—*Foreign Letters, J. A. M. A.*

A Commission to Study Hospital Lotteries.—The government of South Australia appointed a royal commission to inquire whether it is desirable to institute lotteries in South Australia for the purpose of raising funds to assist in the finance of hospitals and other charitable institutions. The Commission took evidence in the different states of commonwealth and had special statistical information about lotteries of Great Britain, Ireland, France, the United States, and Canada. The Commission expressed itself in its report as being not unduly influenced by the religious or ethical aspect. It says it would not have felt justified in coming to its conclusion or objecting to the lottery system on the ground of ethical objection, if on other grounds it had been found desirable. There is a real difference in principle between a government on the one hand taxing private betting or other private activities of the people and on the other hand introducing a lottery for the purpose of raising money for one of its essential social services. In the former case the Government takes no part in the promotion of the activities on which the tax is levied. In the case of a lottery, Parliament either directly or through a department established by it, promotes the lottery for the purpose of profit and takes an active part in inducing people to subscribe to it. No Australian government urges people by advertisement to bet on horse races in order that more revenue may be obtained from betting, or to go to the pictures so that the amusement-tax revenue may be increased, but when there are lotteries the public is definitely encouraged to do so.

Rates, Information and Booklet on Request

(Continued from Preceding Page)

The Commission was much impressed in the course of its investigations by what appeared to be the political repercussions of lotteries either conducted by governments or under a government license. The Commission gained the definite impression that lotteries conducted on the lines of those of New South Wales, Queensland, and Tasmania, tend to become the masters rather than the servants of the government that "controls" them. The Commission considered that the state of affairs tends to demoralize governments. After full and careful investigation the Commission satisfied itself that the lottery does not and cannot solve the hospital finance problem. Even in Ireland the immense Irish sweep has not relieved the Government or the local authorities of their hospital obligations, and in Western Australia and in Queensland lotteries have not helped the Government to any material extent. The existence of lotteries in four of the six Australian states, and the seeming benefits derived from them, give an impression that a lottery is desirable. After thorough investigation, however, the Commission is satisfied that these benefits are more superficial than real.

It may appear difficult to understand why it is that, with all the revenue that lotteries bring in, the Government or local authorities do not secure corresponding relief. There are several contributing factors to this position: (1) The people of Australia are becoming more and more hospital-minded, which means an increasing demand for accommodation. (2) The existence of a lottery tends to create in the people a demand as of right for a much higher standard of hospital buildings and equipment, and for more hospitals. (3) The practice has been generally to use lottery moneys for capital expenditure and, therefore, the cost of maintenance necessarily increases. (4) The existence of a lottery tends to decrease the voluntary contributions for hospital and charitable purposes, and this factor is greatly accentuated when there is a rate or tax for hospitals as well. (5) Where charities are associated with lotteries, the charitable institutions set up higher standards. (6) It may be that one of the reasons why

lottery moneys are spent in the manner in which they are is that such expenditure provides an excellent advertisement for the lottery. For these reasons the Commission found that the establishment of a lottery will not materially relieve the Government or the local governing authorities of their burdens for hospitals or charities. In fact, because of the higher standard that is built up through the expenditure of lottery moneys as capital the ultimate burden is likely to be increased by the existence of a lottery.

Everywhere, says the report, there is a tendency to increase the prizes, and especially the first prize; and everywhere the lottery is an exploitation of the gullibility of the public and the widespread gambling instinct. In fact, so deep-seated has this legalized form of gambling become that it is doubtful whether any government would dare to introduce legislation to abolish these lotteries. The Commission concluded that a lottery as a form of hospital finance provides an unstable method that is demoralizing to the Government, distinctly injurious to traders, and detrimental in the end to the poorer sections of the community, who contribute the bulk of the receipts. If the people who buy lottery tickets can easily afford the money, they can afford to pay their share of the direct taxation necessary to support hospitals. If they cannot afford the money, the state should not take their money. From the establishment of the "golden casket" in Queensland nearly twenty years ago the total receipts amounted to £12,000,000, the prize money amounted to £7,000,000 and the sum paid to hospitals and charities after payment of expenses was £3,000,000. These figures confirm the Commission in its belief that the lottery does not and cannot solve the hospital finance problem and, consequently, it was recommended that the practice should not be permitted in South Australia.—J. Medical Bills in Congress.—Bills Introduced: S. 5, introduced by Senator Sheppard, Texas, for Senator Cope-land, New York, and H. R. 300, introduced by Representa-tive Chapman, Kentucky, propose to prevent the adultera-tion, misbranding and false advertising of food, drugs, devices and cosmetics in interstate, foreign and other com-merce subject to the jurisdiction of the United States. S. 6, introduced by Senator Lundeen, Minnesota, proposes to provide for a nation-wide system of social insurance. A social insurance fund is to be created by an appropri-ation of \$5,000,000,000, from which compensation is to be paid to unemployed, aged or disabled workers. A worker is to be considered disabled if by reason of any physical or mental condition, sickness or handicap he is rendered incapable of total or partial work in his usual or in a suitable occupation, irrespective of fault and irrespective of whether such a disability is the result of accident, illness, disease, physical or mental handicap, or other causes. S. 123, introduced (by request) by Senator Robinson, Ar-kansas, proposes to authorize an appropriation of \$5,000,000 to enable "each state to provide and operate at least one hospital bed for tubercular patients to each annual death from tuberculosis." S. 325, introduced by Senator Hatch, New Mexico, proposes to prohibit the shipment and trans-portion in interstate or foreign commerce of cannabis and its derivatives and compounds, except when shipped or transported for medical and legitimate uses by the pro-ducer, manufacturer or dealer to licensed physicians, sur-geons, dentists, pharmacists, druggists, and veterinarians, under such rules and regulations as shall be prescribed by the Commissioner of Narcotics. A similar bill in the House, H. R. 229, introduced by Representative Fish, New York, proposes to amend the Narcotic Drugs Im-port and Export Act to provide that no cannabis indica, cannabis sativa, or cannabis americana may be imported for the purpose of making marihuana, or for any other purpose. H. R. 119, introduced by Representative Beiter, New York, proposes to extend the benefits of the United States Public Health Service to certain seamen. H. R. 136, introduced by Representative Cochran, Missouri, pro-poses to authorize the Reconstruction Finance Corporation

to make loans to any public or private hospital organized under the laws of any state on the same terms and con-conditions that are applicable in the case of loans to financial institutions. H. R. 216, introduced by Representative Lemke, North Dakota, proposes to authorize the erection of an addition to the existing Veterans' Administration facility, Fargo, North Dakota, such addition to consist of one hundred beds for the care and treatment of general medical and surgical disabilities. H. R. 279, introduced (by request) by Representative Celler, New York, pro-poses to enact a "Workers' Unemployment and Social Insurance Act" and to direct the Secretary of Labor to establish forms of social insurance to pay workers and farmers for loss of wages because of part-time work, sick-ness, accident, old age, or maternity. H. R. 1555, intro-duced by Delegate Dimond, Alaska, proposes to authorize the Secretary of the Interior to establish a hospital for the insane of Alaska. H. R. 1560, introduced by Delegate Dimond, Alaska, proposes to extend the benefits of the United States Public Health Service to any person oper-ating or employed on board certain vessels engaged in fishing operations. H. R. 1952, introduced by Representa-tive Buchanan, Texas, proposes to include the name of Roger P. Ames among those honored by the act recog-nizing the service rendered by Major Walter Reed in the discovery of the cause and means of transmission of yellow fever. H. R. 1962, introduced by Representative Secrest, Ohio, proposes to establish a Bureau of Veterans' Affairs in the Department of the Treasury with the Com-missioner of Veterans' Affairs at the head thereof, to abolish the Veterans' Administration and to transfer its functions to such bureau, to adjust and equalize pensions of veterans and widows and dependents of veterans and for other purposes.—J. Accident Insurance: "Death Resulting From Accidental Suffocation by Gases" Construed.—The defendant insurance company issued to the insured two accident insurance policies in which it promised to pay certain benefits in case the insured died, but limited liability to \$600 in event of "death resulting from accidental suffocation by illuminating or other gases or the accidental taking of any poison." Three days after the policies were issued, the insured was found in his garage overcome by the fumes escaping from the motor of his automobile. He died a few minutes later from carbon monoxid poisoning. The defendant claimed that the death resulted "from accidental suffocation by illuminating or other gases" and that therefore it was liable only to the extent of \$600. The plaintiff, the beneficiary under the policies, brought suit to recover the maximum benefits. The trial court sustained the defendant's motion to withdraw from the jury the question of liability over and above \$600 and, with the consent of the defendant, entered a judgment for the plaintiff for that amount. The plaintiff thereupon appealed to the Supreme Court of Nebraska.

It was not disputed, said the court, that the insured died as a result of his inhaling the fumes from the exhaust of his automobile. That the death was, therefore, caused by the inhalation of gas cannot be denied. In *Birss vs. Order of United Commercial Travelers*, 109 Neb. 226, 190 N. W. 486, it was said:

"The term 'gas' is, in a sense, a generic term and is broad and sweeping in its meaning. In Webster's Unabridged Dictionary it is defined as 'an aeriform fluid; a term used at first by chemists as synonymous with air, but since restricted to fluids supposed to be permanently elastic, as oxygen, hydrogen, etc., in distinction from vapors, as steam, which become liquid on a reduction of temperature. In present usage, since all of the supposed permanent gases have been liquefied by cold and pressure, the term has resumed nearly its original signification, and is applied to any substance in the elastic or aeriform state.'"

The contention of the beneficiary was that death had not resulted from accidental suffocation, relying apparently on medical testimony to the effect that inhaled carbon monoxid gas does not stay in the lungs and does not, therefore, act as a mechanical barrier to respiration. Death results when there is sufficient concentration of carbon monoxid combined with the hemoglobin or red blood cells to displace the oxygen. But, said the court, in construing the contract of insurance, words used therein will be considered as used in their ordinary and popular sense. The definitions or constructions placed on them by the scientist or expert cannot control. "Suffocate," continued the court, is defined in Webster's New International Dictionary as "to kill by stopping respiration, as by strangling or asphyxiation," while the same authority defines "asphyxiation" as "a state of asphyxia; suffocation," and "asphyxia" as "apparent death, or suspended animation, in living organisms, due to deficiency of oxygen and excess of carbon dioxide, specif., in the blood, as in interruption of respiration from suffocation or drowning, or from the inhalation of irrespirable gases." "Suffocation" is defined in Dorland's American Illustrated Medical Dictionary (ed. 16) as "the stoppage of respiration, or the asphyxia that results from it," while the same authority defines "asphyxia" as "suffocation; also suspended animation from suffocation or a deficiency of oxygen in the blood."

In view of these definitions, the court was convinced that a person suffers death as the result of suffocation by gas whether death was due to a deficiency of oxygen in the blood or to an interruption of the physical act of breathing

For Acidity and Allied Conditions, we suggest **ADAMS SPRINGS MINERAL WATER**

● **MANY** physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of these seven known iron and manganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is marked drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

Closing of Houses of Prostitution.—Many foreigners who have visited France, and especially Paris, will be surprised to hear that Mr. Sellier, the present Secretary of Public Health, proposes in the near future not only to close licensed houses of prostitution and to restrict occupancy of hotel rooms to those who have baggage, but also to make the acquisition of syphilis a criminal offense and its treatment obligatory. In an article in the November 15 *Sécle médical*, Dr. Léon Bizard protested against this policy of Mr. Sellier. Doctor Bizard is well qualified to discuss this question, being one of the staff of the St. Lazare Hospital, to which all prostitutes are obliged to go for the treatment of venereal diseases. There are 1,200 "tolerated" houses of prostitution in France and its colonies. The Secretary of Public Health believes that syphilis can be conquered if the houses of prostitution are closed, that the white slave traffic will cease, and that the landlords of the dens of vice will be ruined. Bizard remarks that this plan of freeing the people from sinful

habits and leading them back to the path of virtue is a magnificent one, but that there will soon be a rude awakening to the impossibility of the execution of such a plan. The innumerable hotels, according to the proposed law, will not be permitted to rent rooms to couples without baggage. Bizard remarks that this can be easily circumvented by renting adjacent rooms or perhaps, as he states, there will be created a new trade as now exists in the United States, namely, that of "renting baggage" for a small fee. There will still remain, for those able to pay a higher sum, houses of assignation. The closing of "tolerated" houses will result in increase of street soliciting, which will render control of venereal diseases more difficult than at present, when the inmates of the "tolerated" houses are examined twice a week by medical inspectors of the police departments. The existing system of "segregation," with its strict control, will be superseded by that of "scatteration" and less perfect medical supervision, so that the number suffering from venereal diseases will be greater than at present. Bizard pleads for an amelioration instead of suppression of "tolerated" houses, citing measures taken in Italy, which has prohibited street soliciting but allowed "tolerated" houses to exist without any special signs or lights indicating the character of their trade. Such a plan will do more to check venereal diseases than that of forcing prostitutes to go on the streets.—*J. A. M. A.*

Dedication of Eastman Dental Clinic in Paris.—Work has progressed so rapidly on the million-dollar Eastman Dental Clinic, now under construction in Paris, that Dr. Harvey J. Burkhart, director of the Rochester Dental Dispensary and general administrator of the Eastman Foundation, announced recently that it is hoped to finish the entire building in time to hold the dedication ceremonies on July 4, 1937. The president of the French Republic, Mr. Lebrun, Ambassador William C. Bullitt,

(Continued on Page 44)

The first formula must agree with the baby!

NEWBORNS require breast milk. Deprived of human milk, their nutritional requirements are met by simple mixtures of cow's milk, sugar and water. The milk may be fresh, evaporated, dried, sweet or sour; the sugar simple or mixed.

Whole milk formulas are suitable for most newborns with good digestive capacities. The amount of whole milk given should approximate $\frac{2}{3}$ of the total required calories. And the remainder ($\frac{1}{3}$) should be in added Karo. Water is added to the mixture for the fluid intake to be about $2\frac{1}{2}$ ounces per pound of baby weight per day.

Evaporated milk formulas are indicated for newborns with limited digestive capacities. They may be used to advantage in considerably higher concentrations than whole milk for premature, feeble and debilitated infants. *The added Karo is again one-third of the total required calories.*

Dried milk formulas are suitable for allergic infants who will take only small volumes at a feeding and for babies of allergic parents. Formulas approximately equivalent to whole milk may be made up with water and Karo added in the same ratio as in whole milk mixtures.

Acid milk formulas are of particular value for babies with low digestive capacities requiring large food requirements. Acid milk requires no dilution with water. The amount of Karo required may be

added directly to the total volume of acid milk prescribed.

Karo is an excellent milk modifier of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor) for both the baby and the budget.

FORMULAS FOR THE NEWBORN

3 Ounces; 6 Feedings

Whole Milk	10 ounces
Boiled Water	10 ounces
Karo	2 tablespoons

Evaporated Milk	6 ounces
Boiled Water	12 ounces
Karo	2 tablespoons

Powdered Milk	5 tablespoons
Boiled Water	20 ounces
Karo	2 tablespoons

Lactic Acid Milk	12 ounces
Boiled Water	8 ounces
Karo	2 tablespoons

and a number of other leading French and American personalities will be invited to take part in the ceremonies. The clinic was designed to provide free dental service for children less than sixteen years of age who are unable to pay. The clinic occupies a large area, and the open land surrounding the clinic will be converted into parks and playgrounds. The work of the Paris Eastman Clinic will be based on that carried out at Rochester, and it should serve as a center for dentists and dental surgeons to carry on research and postgraduate work. It will also aim to teach children and parents the need and value of regular dental work throughout their lives.—J. A. M. A.

Feeding the Dionne Quintuplets.—The January *Journal of the Canadian Medical Association* contains a detailed account of Dr. Allen Roy Dafoe, of his management of the famous Dionne Quins, during the first year of their lives.

They were kept in incubators until each one reached the weight of six pounds.

A mixture of oxygen 95 per cent with carbon dioxide 5 per cent was given to them for the first three months as a stimulant. Once a day they were given an oil bath.

Anemia, which early developed, was treated by small doses of ferrous chlorid.

Sunlight and fresh air were early and frequently utilized in the program, with excellent results.

On the first day they were given, every two hours, ten or fifteen drops of warm water with an eye dropper. Every two hours, on the second and third days, each had from thirty to sixty drops of a mixture containing seven ounces of milk, thirteen ounces of water, and one ounce of corn syrup.

From the fourth day until October 19, they were kept on breast milk. They were then placed on a mixture of

cow's milk and Dextri-Maltose. After a few days evaporated milk was substituted for cow's milk with the addition of lacto-bacillus acidophilus.

This formula was used until the children were one year old.

At the second month they were given vitamin D in the form of viosterol.

The first solid food was used on October 26 in the form of Pabulum, which was given daily from that date.

Assorted vegetables and fruits cooked and strained were also used in the diet.

The nutritional improvement in the children was satisfactory throughout.

Their management by Doctor Dafoe reflects great credit on his professional skill.

The world justly applauds him on his success.

Entire Freedom From Tuberculosis of Cattle, Is United States Aim.—With the continued coöperation of public officials, veterinarians, livestock owners, and others who have aided in the aggressive fight against bovine tuberculosis, leaders in the work hope that eventually this disease will be entirely eradicated. In forty-three states the prevalence of bovine tuberculosis has already been reduced to less than one-half of one per cent. These developments were the basis of an address by Dr. John R. Mohler, Chief of the United States Bureau of Animal Industry, at an Achievement Day celebration at Harrisburg, Pennsylvania. The event celebrated federal recognition of Pennsylvania as a modified accredited area, signifying the reduction of bovine tuberculosis throughout the state to less than one-half of one per cent. . . .

Medicine is as old as the human race; as old as the necessity for the removal of diseases.—Heinrich Haeser.

WE do not claim that Poland Water is a cure for any disease: We offer it as a water extremely pure—chemically and bacteriologically—that is neutral and that may be an addition to your armamentarium.

Malpractice: Liability of Physician for Abandonment of Patient.—The defendant, a physician, was engaged to attend the plaintiff during the latter part of her pregnancy. Prior to her confinement she had a "hemorrhage," the date of which is not given in the record. About three weeks thereafter, in the early afternoon, she had another "hemorrhage" and the defendant was called and attended her at her home. The patient continued to lose blood and to suffer pain, and at midnight the defendant again responded to a call. Shortly after eight o'clock the following morning the defendant, at the behest of the plaintiff's husband, called on the patient and found her still bleeding and in severe pain. Arrangements were immediately made to transfer the patient, in an ambulance, to a hospital. The defendant did not accompany the patient. On her arrival at the hospital she was cared for by nurses, who "gave her pills, injections, and so on." Later two physicians, apparently at the instance of the hospital authorities, attended the plaintiff. During this time the plaintiff's husband and others made repeated attempts by telephone to get in touch with the defendant, but he could not be located. He did not appear at the hospital until three o'clock that afternoon, either just before or after the plaintiff gave birth to a child that did not survive. In a suit subsequently instituted by the plaintiff against the defendant, she alleged that he was guilty of a breach of his professional duty in that he neglected to accompany her to the hospital, failed to be present during her labor and childbirth, and failed to render such treatment as would have stopped her bleeding and insured the delivery of a living child. She sought recovery of damages for pain which she had suffered and would continue to suffer, and for great mental and physical anguish caused by her having given birth to a dead child. The trial court directed a verdict for the physician and, from the judgment entered on that verdict, the plaintiff appealed to the Supreme Court of Michigan.

The Supreme Court did not pass on the plaintiff's contention that she was legally entitled to the personal care

*Ralston cooks
in 5 minutes*

**The Hot Whole
Wheat Cereal
Enriched with
Extra Vitamin B**

Many of them must serve hurry-up breakfasts. Many are pressed for time. So when you recommend Ralston, make doubly sure they follow your advice by telling them Ralston cooks so quickly... We believe you'll agree this is important because Ralston is...

• **A WHOLE WHEAT CEREAL...**

with only the coarsest bran removed... providing an abundance of the body-building, energy-producing elements that came from choice whole wheat.

• **DOUBLE-RICH IN VITAMIN B..**

pure wheat germ is added to Ralston to make it $2\frac{1}{2}$ times richer in vitamin B than natural whole wheat.

• **PALATABLE AND ECONOMICAL**

... tastes so good that the whole family likes it—and each generous serving costs less than one cent.

and attendance of the defendant. It did say that the evidence showed that, through the defendant's arrangements for her removal to the hospital, she had received professional care and attention and that there was no competent testimony that the defendant's failure to attend her in person resulted in her suffering any greater pain than she otherwise would have suffered, or that the unfortunate outcome of her confinement was caused by his absence. Furthermore, in the opinion of the court, the record failed to show that the defendant by proper care could have and should have caused cessation of her hemorrhages. In short, the plaintiff failed to show, the court concluded, that she would have suffered less or that she would have escaped any of the elements of damages for which she sought recovery had the defendant attended her in person during the interval he was absent instead of causing her to be placed under the care of other skilled persons. The judgment for the defendant was affirmed. (*Jackowicz vs. Knobloch* (Mich.), 265 N. W. 799.—*J. A. M. A.*)

Victory and Defeat.—However large or small our part, we can all feel with Theodore Roosevelt, who said: "It is not the critic who counts; not the man who points out how the strong man stumbled, or where the doer of deeds could have done them better. The credit belongs to the man who is actually in the arena; whose face is marred by dust and sweat and blood; who strives valiantly; who errs and comes short again and again; who knows the great enthusiasms, the great devotions, and spends himself in a worthy cause; who at the best knows in the end the triumphs of high achievement; and who at the worst, if he fails, at least fails while daring greatly; so that his place shall never be with those cold and timid souls who know neither defeat nor victory."

"Negligence, indifference, ignorance, and false economy—not the Lord—make the death rate high."

When Steers Had Long Horns

THE medicinal value of the glands of internal secretion was not recognized.

But times have changed, as well as cattle. Now, the therapeutic value of certain gland products is definitely established and each year adds to our knowledge in this important field of therapeutics.

To the physician prescribing gland products we urge specification of "Wilson," because it connotes a product made at the source of supply from fresh glands, processed promptly, with the aim of conserving maximum hormone activity, in a laboratory devoted exclusively to the endocrine field.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

Mildly Antiseptic, Emollient and Astringent

Ichthyol may be used externally in any strength. For various skin affections and on joints, a 5%-50% ointment; for tampons, a 10%-25% solution in glycerin or water; for douching, a 2% solution, are usually recommended. It may be incorporated with cacao butter for rectal or vaginal suppositories. Washing in boiling water readily removes Ichthyol stains from fabrics.

"You'd dub fewer shots,
Bill, if you cleaned up
that *Hay Fever* with
Pollen Extracts"

CUTTER POLLEN EXTRACTS

"clean up" hay fever with a
minimum of fuss and bother

Cutter *test sets*, split up according to season and geographical region, eliminate non-essentials and avoid the confusion (in choosing the proper pollens for treatment), of reactions to pollens which are either not indigenous to the patient's locality, or whose pollenating dates do not coincide with the patient's symptoms.

Cutter *treatment sets* are made up to your prescription, and each set of serial dilutions contains more than 150,000 pollen units—five to ten times the pollen unitage in the average "treatment set," but not more than enough in many cases.

Test sets—\$1.50. Treatment sets—\$9.00 plus \$.50 for each additional pollen where more than a single pollen is required.

FOR HER BABY, RECOMMEND STRAINED FOODS BEARING—

1.  A SEAL YOU VALUE HIGHLY
2.  A SEAL SHE UNDERSTANDS

Every day, an increasing number of doctors give their active recommendation to Heinz Strained Foods for infants and soft diet cases.

One reason is that Heinz Strained Foods bear the Seal of Acceptance of the American Medical Association's Council on Foods. This means that they have been carefully investigated and officially accepted by your exacting profession.

Secondly, Heinz Strained Foods bear the famous "57" Seal of Quality. For over 50 years women have looked to this insignia as a hallmark of pure, safe and wholesome foods. They have never been disappointed.

Recommend strained foods that have *both* the backing of your official body and the high esteem of experienced housewives and mothers throughout America. Suggest *Heinz!*

HEINZ STRAINED FOODS

11 KINDS—1. Strained Vegetable Soup. 2. Mixed Greens. 3. Spinach. 4. Carrots. 5. Beets. 6. Peas. 7. Prunes. 8. Cereal. 9. Apricots and Apple Sauce. 10. Tomatoes. 11. Green Beans.

EMMENIN

The orally active, oestrogenic placental
extract elaborated by Dr. J. B. Collip, De-
partment of Biochemistry, McGill University.

*(Canadian Medical Association Journal,
February, 1930.)*

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our
laboratories, we have been able to render
Emmenin entirely free from disagreeable
taste and odor. This has been accomplished
without loss of therapeutic activity, and the
potency is ensured by carefully controlled
biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and stand-
ardized under direct control of the Depart-
ment of Biochemistry, McGill University.

Meeting, <i>Second Tuesday.</i>

A Palatable Time-tested Vitamin Vehicle . . .

THE oily consistency usually associated with vitamin bearing oils is lacking in MALTINE WITH COD LIVER OIL.* This fact is most readily recognized and appreciated by both physician and patient. MALTINE WITH COD LIVER OIL is an effective and palatable agent for administering Cod Liver Oil values, including vitamins A and D. It also contains vitamins B and G and other nutritive factors, not found in any fish-liver oil. MALTINE WITH COD LIVER OIL and Iron Iodide is also available. This product contains two grains of freshly prepared Iron Iodide per fluid ounce. The Maltine Co., 60 Hudson Street, New York City.

*Maltine 70%, cod liver oil 30%

VITAMIN REQUIREMENTS OF MAN

I. VITAMIN C.

• Vitamin C is known to play an important role in human nutrition. Severe deficiency of this factor results in scurvy. It has been estimated by the Committee on Nutritional Problems of the American Public Health Association (1934) that the minimum daily intake of vitamin C (cevitamic acid) required to protect against scurvy increases from approximately 100 International units (5 mg. cevitamic acid) for the infant to 300 International units (15 mg. cevitamic acid) for the adult (1).

Vitamin C intake of this order of magnitude prevents the development of clinical scurvy, however, it is probably inadequate for optimum nutrition. Clear cut cases of scurvy seldom are seen in this country although some authorities believe that symptoms of a mild deficiency of vitamin C are not uncommon (2).

Referring to nutritional deficiency diseases in general it has been said that, "Almost every tissue in the body may be affected by a deficiency in a food factor" (3).

The tissues generally recognized as affected by deficiency of vitamin C are the endothelium of the blood vessels and the teeth. It has been suggested that to prevent the development of subclinical symptoms, a daily intake of 380 to 540 International units of vitamin C is required for a 130 pound adult (4).

Thus it would appear that the optimum in-

take of vitamin C is at least twice the amount required to protect against scurvy.

Data recently published demonstrate that the vitamin C content of human milk is dependent upon the vitamin C content of the maternal diet (5).

Hence when the diet of the lactating mother is low in vitamin C, this factor is also deficient in the milk.

The League of Nations Technical Commission recommends an intake of over 500 International units per day during pregnancy and lactation (6).

The inclusion in the diet of liberal quantities of fruits and vegetables, prepared in such a manner as to retain a major portion of the original vitamin C content, may be relied upon to supply the need for this vitamin. The value of commercially canned foods as anti-scorbutics has been repeatedly demonstrated during the past decade (7).

More recently, the vitamin C content of many commercially canned fruits and vegetables has been determined and the results expressed in International units (8).

Consideration of two factors, namely, the quantitative requirement of the human for vitamin C, and the vitamin C potencies of commercially canned fruits and vegetables, emphasizes the value of these protective foods as sources of vitamin C.

This is the twenty-second in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Council on Foods of the American Medical Association.

CO-OPERATE WITH YOUR ADVERTISERS

CALIFORNIA AND WESTERN MEDICINE, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention CALIFORNIA AND WESTERN MEDICINE.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this JOURNAL to members and readers.

A SERVICE AGENCY—FOR READERS

THE JOURNAL of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely free to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in CALIFORNIA AND WESTERN MEDICINE, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. CALIFORNIA AND WESTERN MEDICINE and the A. M. A. Service Bureau desire to serve you.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE

(In affiliation with COOK COUNTY HOSPITAL)

Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses.

SURGERY—General Course One, Two, Three and Six Months; Two Weeks Intensive Course Surgical Technique (Operative Surgery with Practice); Clinical Course.

GYNECOLOGY AND OBSTETRICS—Four Weeks Intensive Course starting May 3rd.

FRACTURES AND TRAUMATIC SURGERY—Informal Practical Course; Ten-Day Intensive Course starting April 12, 1937.

EAR, NOSE AND THROAT—Informal Course; Personal Courses; Intensive Two Weeks Course starting April 5, 1937.

OPHTHALMOLOGY—Intensive Two Weeks Course starting April 19, 1937.

UROLOGY—General Course; Two Months; Intensive Course Two Weeks; Special Courses.

CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

GENERAL, INTENSIVE AND SPECIAL COURSES IN ALL BRANCHES OF MEDICINE AND SURGERY starting every week.

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 South Honore Street, Chicago, Ill.

ABDOMINAL SURGERY

The Continuous Course Is Now in Session

STUDENTS MAY ENTER AT ANY TIME

The following subjects will receive special attention:

Stomach and duodenum, colon and rectum, gall-bladder and bile ducts, small intestines.

The work will be given every Tuesday from 11 a.m. to 3 p.m. Those desiring to divide the work into two sessions may report on Tuesdays and Thursdays from 11 a.m. to 1 p.m. The fee is \$15 per month.

Applicants must be graduates of schools approved by the State Board of Medical Examiners

For descriptive circular and further information inquire of

CALOMEL DIASPORAL

Intravenous. Each 5 c.c. 10 mg. Fournier considered that of all the mercurials used in the treatment of syphilis, Calomel was the most effective.

Hazen, in his book, "Diseases of the Skin," states: "Calomel is considered the most powerful anti-syphilitic drug at our disposal, with the exception of arsphenamine and neoarsphenamine."

Haut und Geschlechtskrankheiten, J. Jadassohn. The germicidal efficiency of mercury bichloride ($HgCl_2$), while containing less mercury than other mercurial compounds, is nevertheless more efficient as a germicide. The reason for this is obvious when we consider it from the standpoint of ionization. In $HgCl_2$ there is a rapid dissociation of the ions, which accounts for its superior destructive action upon bacteria.

However, in treating syphilis with mercury, we desire the opposite effect, that is, a mercurial compound in which the dissociation of the ions is slow in order to obtain continuous stimulation of the cells. Calomel, due to the slow dissociation of Hg ions, is therefore superior therapeutically and less toxic than other mercurials in the treatment of syphilis. 10s, \$4.00; 50s, \$16.00.

Decholin

REG. U.S. PAT. OFFICE
Riedel-de Haen, Inc.

Flushes the Entire Biliary System

Decholin augments the production of bile by the liver cells 100-200%, thereby flushing the entire biliary drainage system from the smallest bile channels to the ductus choledochus and gall bladder. * * * Decholin is a single chemical entity, no cathartics are added. It acts directly upon the liver parenchyma, and it does not produce undesirable purgings. Decholin is of accepted value in chronic cholecystitis, cholangitis, hepatitis of toxic origin and functional hepatic insufficiency.

**NUTRI-AD
ARTHROPHYLL**

(6)

A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » » »

NUTRI-AD—ARTHROPHYLL (6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL (6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

Protamine Zinc Insulin, Squibb.—Physicians have
been advised that Protamine Zinc Insulin, Squibb, is now
available. The new form of treatment which this new
preparation now makes possible has been declared the
most notable advance in the treatment of diabetes since
the discovery of insulin in 1921.

Protamine Zinc Insulin is slowly absorbed, and the
duration of action of a single dose is about three to six
times that of unmodified insulin. For most patients, one
injection a day is adequate. It is indicated chiefly in those

diabetics particularly difficult to control with unmodified
insulin because of the frequency of hypoglycemic reactions
and the necessity for several daily injections of insulin.
However, because it is slowly absorbed Protamine Zinc
Insulin is *not* recommended in cases of diabetic coma, in
diabetes complicated by infection, or in the event of surgi-
cal operation.

Protamine Zinc Insulin, Squibb, is marketed under
license from the Insulin Committee, University of To-
ronto. It is supplied in 10 cubic centimeter vials ready for
use. The preparation appears milky because the insulin
is in suspension. Each cubic centimeter, after it has been
brought into uniform suspension, contains 40 units of
insulin together with protamine and 0.08 milligrams of
zinc. It is stable in the cold for not less than six months
and should not be used after the expiration date stamped
on its wrapper. Protamine Zinc Insulin should be adminis-
tered only subcutaneously.

It is the prediction of a renowned authority that as a
result of the new treatment now available, severe dia-
betics will improve, the benefits of insulin therapy will be
extended to larger numbers of mild diabetics, complica-
tions will be reduced, and more lives of diabetics will be
prolonged and maintained in comfort.

SAILING

SELLING

... to reach your destination
you must chart your course

●

7 POINT program for DIRECT MAIL SUCCESS

1. *Intelligent plan*
2. *Sound copy*
3. *Attractive design*
4. *Significant illustration*
5. *Good printing*
6. *Correct circulation*
7. *Barry's coöperation*

Special attention given to "Point 7" will insure proper consideration of the other six points. Call our Creative Department when planning your next printing. There's no obligation, of course.

Intelligent direction is what keeps a ship on its course and assures safe arrival at its destination. Never would the captain set sail without a dependable compass and reliable charts.

The creation of a direct mail campaign should never be impulsive and ill-considered. It is futile to proceed until a substantial basic plan has been developed. Decide upon the load that must be carried, then build the vehicle to carry it.

The initial cost of intelligently planned direct mail advertising is no more than "hit or miss" production—and the results explain why so many representative advertisers consistently return to this firm for Planned Printing.

BOOK REVIEWS

(Continued from Page 14)

The Colon as a Health Regulator. By Sir Henry M. W. Gray, Aberdeen. Pp. 100. Price, \$2. New York: The Macmillan Company.

Setting forth the author's personal views upon the function of the colon and its influence on health. Nothing new or important is advanced.

Handbook of Ocular Therapeutics. Second Edition. By Sanford R. Gifford, M. A. M. D., Northwestern University. Pp. 340. Philadelphia: Lea & Febiger.

This second edition is an improvement, brought up to date by additions on vitamins, glandular extracts, contact dermatitis, keratitis, corneal dystrophy, and the use of heat and cold.

It is a concise text on ocular therapeutics. Therapeutical measures are presented in a clear manner, and indications are cited.

Should serve as a useful guide for quick reference because it is dependable.

Medical Morals and Manners. By Hubert A. Royster, M. D. Pp. 333. Price, \$2.50. University of North Carolina Press.

Doctor Royster has compiled an interesting series of chapter comments upon practice, professional conduct, public relations, and personal observations and experiences. They are based on his writings and public contacts during forty years of surgical practice.

Doctor Royster does not sermonize. His statements and advice are sound. He has observed them in the years of distinguished service to his state and nation as well as in private practice. He dignified his profession.

To young physicians, yes, and to older men, this volume is recommended. It will profit them to read and ponder upon the sage advice given. Every hospital and college library should have this volume on its library shelves.

TWENTY-FIVE YEARS AGO

(Continued from Text Page 216)

Obituary.—Henry Gibbons, Jr., M. D., was born in Wilmington, Delaware, September 24, 1840. His father was Henry Gibbons, M. D., later on one of the best known and appreciated physicians in California; he was an excellent practitioner, teacher, and lecturer. For many generations Dr. Henry Gibbons' ancestors were Quakers. He came to California in 1850. Dr. William Gibbons of Alameda and Dr. Edward Gibbons of Oakland, California, both now dead, were his brothers. . . .

SEATTLE, PORTLAND AND TACOMA

Dr. Henry Gibbons, Jr., came to California via the Isthmus with his mother and four sisters in 1851. They lived in San Francisco, California, until 1863. He attended the high school in San Francisco and was graduated from there in 1859. He then commenced the study of medicine at the earnest request of his father, but was strongly inclined to higher mechanics, having natural gifts in that direction. . . .

He was a highly moral man in every particular. In more recent years he was a trustee of First Unitarian Church.

He married Marie Raymond in 1871. She died in 1899. Their children are Dr. Morton R. Gibbons, Dr. Henry W. Gibbons, Miss Ida L. Gibbons, Miss Miriam Gibbons, of San Francisco, California, Mrs. E. M. Shinkle (wife of Major Shinkle, U. S. A.), and Mrs. Perry Evans of Berkeley, California.

In the death of Doctor Gibbons this community has met with a severe loss. He lived in an age and under such

TWENTY-FIVE YEARS AGO

(Continued from Preceding Page)

circumstances that he was peculiarly valuable to many, for whom he was glad to do. Thousands in San Francisco are indebted to him for life, health and resultant happiness. His special practice placed him in a confidential position that was never betrayed. The poor, or a friend, never called on him in vain, and the young physician had his eye, hand, ear, and heart at command. . . .

From an Article on "Variations in the Tonicity of the Abdominal Musculature and Their Significance" by J. L. Lohse, M. D., Oakland.—The selection of this subject for a paper was determined upon by the conviction that a great and unwarranted lack of consideration has been given to one of the most important systems of our body, namely, the muscular system; and that by this neglect much is overlooked that has a direct bearing upon the prevention of disorders as well as upon their correction when once they are an established condition. Our failure to appreciate its importance has left open a large field which is responsible for the founding of many large schools for the teaching of irregular practitioners. . . .

From an Article on "The Management of Cases of Pulmonary Tuberculosis, with Remarks on Treatment" by R. A. Peers, M. D., Colfax.—Mr. President, Members of the California Academy of Medicine, and Visitors: It is with no small degree of trepidation that I address you on the subject of tuberculosis. I feel that with the immense amount of interest in this subject which has been stimulated by the studies and writings of others and the vast amount of literature bearing upon the treatment of tuberculous patients, it will be extremely difficult for me to bring before you anything that has not already been said or that can possibly be considered new. I have thought, however,

that it would possibly be of interest to you to give in some detail a description of the methods which have afforded me a certain degree of success in the management of these cases. I use the word "management" in preference to "treatment" because at present we have no treatment for tuberculosis. True we have drugs that are of value in the control of certain symptoms and a so-called specific therapy which in some selected cases influences favorably the course of the disease, but nothing that can be called a treatment. The road to success lies in the proper management of the patient's daily life—a regulation of his hours of rest, exercise, diet, and entire environment. . . .

From an Article on "Medical Laws of California" by Clarence F. Lea, Santa Rosa.—California, in common with most of the other states of this country, has attempted to regulate the practice of medicine. In 1876 the legislature passed an act specifying the requirements for the right to practice medicine and providing for a State Medical Society, who had charge of issuing certificates to persons who established their right to certificates to practice; said Medical Society was also given power to refuse the right to practice to individuals guilty of unprofessional conduct, and for similar cause they could revoke certificates to those who were practicing. In that original act a person practicing medicine was defined to be one "who shall profess publicly to be a physician and to prescribe for the sick, or who shall append to his name the letters of M. D." . . .

From an Article on "Treatment of Vascular Naevi with Carbon Dioxid Snow" by G. H. Mize, M. D., San Francisco.—It is not my desire this evening to furnish an exhaustive treatise on carbon dioxid snow and the microscopical changes resulting in the tissues from its use, but to present to you the salient points in the preparation and the clinical utilization thereof. . . .

(Continued on Page 20)

For Children's Colds

In prescribing 'Benzedrine Inhaler' for children's head colds, you are providing a first aid remedy which may prove of constant service.

At the first sign of a cold the child is instructed to use the inhaler. Since benzyl methyl carbinamine is volatile, it penetrates to areas not readily accessible to liquid inhalants, and there is no oil to be aspirated and become a potential source of later trouble by accumulating in the lungs. (Graef—Am. J. of Path., Vol. xi: No. 5, Sept. 1935.)

For the adult members of the family, 'Benzedrine Inhaler' is equally useful.

Each tube is packed with benzyl methyl carbinamine, .325 gm.; oil of lavender, .097 gm.; menthol, .032 gm.

'Benzedrine' is the trade mark for S. K. F.'s nasal inhaler and for their brand of the substance whose descriptive name is benzyl methyl carbinamine.

TWENTY-FIVE YEARS AGO

(Continued from Page 18)

From an Article on "A Case of Partial Tremulous Scrivener's Palsy: The Psychogenesis of Which Was Discovered in One Interview Which Led to Recovery Through the Patient's Own Effort" by Tom A. Williams, M. B., C. M.—A naval paymaster, aged thirty-two years, single, was referred to me early in 1908 by his brother, a physician in Boston, because when he returned to work after the drainage of a large perityphlitic abscess which discharged for a month, he found that his signature was no longer uniform. Instead of improving, he became worse with practice; and although his other writing was not so seriously impaired he had ceased writing entirely and conducted his correspondence by dictation and signatures. . . .

The American Medical Association Press Service to Newspapers.—The following is a circular letter sent out by the Press Bureau of the Council on Health and Public Instruction to all the five thousand and more papers on its list. In many instances the papers published this letter in full. It will show you a little of the attitude and of the nature of the work of the Association in connection with publicity. . . .

Attacks on the Association.—For some time past, the American Medical Association has been the subject of attack. Attempts have been made to mislead the public as to what it is and what it is doing. The newspapers themselves have originated very little of the "copy" used. It has been inspired by, and, in most cases, prepared by, those who have good reason to be hostile to the American Medical Association.

An organization has recently arisen whose principal object seems to be to attack the American Medical Association under cover of opposition to its origin to those who were and are being injured by the work of the Association.

THE BEST TEST IS THE CLINICAL RESPONSE

Here is an opportunity to prove that endotoxic infections respond rapidly when treated with

EDWENIL

the polyvalent, protein-free, antibacterial agent. The salient points are these:

- (1) The promptness of the response; the defenses are aroused immediately, resulting in a "shower of antibodies."
- (2) There are no detrimental "reactions" nor unpleasant anaphylactic phenomena.

Edwenil is indicated in all endotoxic bacterial invasions—**respiratory infections, such as pneumonia, influenza, and colds;** septic conditions, such as abscesses, boils, and carbuncles; acute specific fevers, such as whooping cough and measles.

THE WORLD'S MOST FAMOUS NATURAL STILL ALKALINE WATER

TWENTY-FIVE YEARS AGO

(Continued from Page 20)

The American Medical Association has no secrets. It has no desire to keep from the public what it is doing. On the contrary, it wants the public to know what it is doing. It will then be apparent why the Association has incurred the enmity of certain interests.

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 216)

to practice. The three had been fined \$100 each for violating the Act. They said they were graduated from the California University of Liberal Physicians and held licenses from the city of Hawthorne to practice. The trio then sought to take the dispute into federal court by asking the injunction on the ground the California law violated the Federal Constitution. The appellate court agreed with the Federal District Court at Los Angeles that there was no federal question involved." (Oakland Tribune, February 16, 1937.)

"Governor Frank F. Merriam has just completed twenty-two appointments to various State regulatory boards. . . . The Governor reappointed Dr. C. E. Schoff of Sacramento and Dr. W. S. Geistweit, Jr., of San Diego to the Board of Medical Examiners. . . ." (Los Angeles Journal, February 16, 1937.)

"A federal court jury convicted today two Milwaukee lawyers and a New Orleans resident of mail fraud. They were accused of swindling sufferers of eye diseases in operations which the Government contended netted a nation-wide ring \$20,000,000 in twenty years. The de-

fendants were Frank Mackett, Jr., and William Haney of Milwaukee and Samuel Birnstein of New Orleans." (Associated Press dispatch dated Milwaukee, January 22, 1937, printed in the San Francisco Call-Bulletin, January 22, 1937.)

"The right of physicians to testify as to the effect of any kind of treatment for tuberculosis was affirmed by Superior Judge Carl Stutsman in a case concluded yesterday in his court, wherein a jury awarded a \$10,000 judgment against a local chiropractor for malpractice. The suit followed the death of a 6½-year-old boy, who, suffering from tuberculosis of the spine, in the neck area, received four and one-half months of chiropractic treatments. . . . Testimony of physicians appearing as expert witnesses was that the proper treatment of tuberculosis is no treatment, or immobilization, and the court sustained the right of representatives of the medical profession to testify against chiropractors to this extent." (Los Angeles Journal, January 19, 1937.)

"Repercussions of the smashing of the huge Pacific Coast illegal operations ring here a few months ago were heard again today, following the death yesterday of Mrs. Eva Cooke Louis, 21-year-old housewife. Victim of complications following an alleged illegal operation, her death, officers said, may reveal a hitherto undisclosed link in the coast-wise chain. Mrs. Louis was taken to Torrance Memorial Hospital last Sunday in a serious condition. The physician who had performed the operation upon her on January 14 disappeared when complications set in. . . ." (Los Angeles Herald-Express, January 23, 1937.)

"Gypsy Dan Chandler, Indian medicine man, was sentenced to 180 days yesterday by Municipal Judge Dawson
(Continued on Next Page)

LIVERMORE SANITARIUM

The Hydropathic Department devoted to the treatment of general diseases excluding surgical and acute infectious cases. Special attention given functional and organic nervous diseases. A well equipped clinical laboratory and modern X-ray Department are in use for diagnosis.

The Cottage Department (for mental patients) has its own facilities for hydropathic and other treatments. It consists of small cottages with homelike surroundings, permitting the segregation of patients in accordance with the type of psychosis. Also bungalows for individual patients, offering the highest class of accommodation with privacy and comfort.

GENERAL FEATURES

1. Climatic advantages not excelled in United States. Beautiful grounds and attractive surrounding country.
2. Indoor and outdoor gymnastics under the charge of an athletic director. An excellent Occupational Department.
3. A resident medical staff. A large and well trained nursing staff so that each patient is given careful individual attention.

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

for practicing medicine without a license. Gypsy Dan was operating a herb and snake-oil store at 113 East Fifth Street, according to John Ronan, Special Agent of the State Board of Medical Examiners." (Los Angeles Times, January 27, 1937.)

"One man was a blackmailer. Another was a highway robber. A third tried to kill a man. A dozen more were auto thieves, burglars, and professional thugs. And all were turned loose on parole. In other words, the parole boards turned society over to these desperadoes so they might continue their lawlessness. What were the results? Those same men are now being hunted frantically by G-Men for practically every crime on the calendar—including kidnaping and murder. . . . Just so many 'noble experiments' gone wrong. With the joke on the public—as usual." (Editorial from San Francisco Call-Bulletin, February 4, 1937.)

"Arguments on the petition of Dr. George W. O'Donnell of San Francisco for the renewal of his license as a practicing physician were heard before Superior Judge Malcolm C. Glenn today. Doctor O'Donnell's license recently was revoked by the State Board of Medical Examiners on the ground he performed an abortion. The physician was represented by Attorney Percy G. West of Sacramento." (Sacramento Bee, February 3, 1937.)

"The 'cure' for tippling kicked back on the 'doctor' today. Harry B. Miller, manager of the Samaritan Treatment Sanitarium, 1222 Lake Shore Drive, Oakland, was charged with having drunk so much he was forced to become a patient. John D. Owen, owner of the sanitarium, brought suit in Alameda County Superior Court to force

an accounting and obtain an injunction against Miller's management—Owen called it 'mismanagement.' Owen demanded accounting of \$1,600 in sanitarium funds and an injunction removing Miller as manager. 'Miller got so drunk he had to take the cure himself,' Owen told the court. Miller did not appear. A temporary injunction was granted until Miller can be present in court." (San Francisco Call-Bulletin, February 15, 1937.)

"Losing their long battle for reversal of their convictions on narcotic charges, Dr. Edward H. Williams of Los Angeles and Dr. Frank T. Cary of Inglewood yesterday were denied review of their cases by the United States Supreme Court. The tribunal, according to dispatches from Washington, refused to review judgments against the physicians by the Ninth Circuit Court of Appeals. Doctor Williams, former head of the Los Angeles narcotic clinic, was indicted on five counts for selling, bartering and dispensing narcotics to addicts by means of a prescription. He was convicted on one count. It was the Circuit Court's ruling that an assignment of errors by the federal trial court here was not filed within the time allowed. Doctor Williams, a noted psychiatrist, was placed on two years' probation by Federal Judge Harry Hollzer. Doctor Cary was convicted on five counts and was sentenced to serve twelve months in a federal road camp on three counts of the indictment, to run concurrently, and was placed on five years' probation on the remaining counts. Both physicians denied unlawful issuance of prescriptions." (Los Angeles Examiner, February 9, 1937.)

"Efforts by attorneys for four physicians convicted in the recent sensational Pacific Coast operations ring trial to obtain continuances before the State Board of Medical Examiners of trials for their clients on revocation of licenses were denied today as the Board resumed sessions

(Continued on Page 27)

Old Way...

CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.

*Frazer, J. G.: *The Golden Bough*, vol. 1, New York, Macmillan & Co., 1928

It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

New Way...

Preventing and Curing Rickets with OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a natural vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets,

regardless of degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

Mead's Oleum Percomorphum is not advertised to the public and is now obtainable at drug stores at a new economical price in 10 c.c. and 50 c.c. bottles and 10-drop capsules.

MEAD JOHNSON & COMPANY, Evansville, Indiana, U. S. A.

BOARD OF MEDICAL EXAMINERS

(Continued from Page 24)

in Foresters' Hall, 1329 South Hope Street. Continuances were asked on grounds that the three physicians have appealed their convictions in Superior court and that the Medical Board should not act to revoke their licenses until all court action is completed. The physicians in question are: Dr. James H. Beggs, Oakland; Dr. Jesse C. Ross, San Francisco; Dr. Alfred Henry Valentine St. John and George E. Watts, both of Los Angeles. . . . (Los Angeles *Herald-Express*, February 9, 1937.)

"The conviction of Dr. Thomas P. Ratigan, Jr., prominent Seattle physician, who, according to federal officials, made more than \$100,000 in one year by illegal sale of narcotics, was affirmed by the United States District Court of Appeals here yesterday. In its ruling the court approved the sentence meted out to the doctor in Seattle of seven years in a federal penitentiary and a fine of \$10,000. Doctor Ratigan was arrested and convicted in the northern city, and his attorneys appealed the conviction." (San Francisco *Examiner*, February 24, 1937.)

Mrs. Hilma Thompson, fifty-seven, was found critically injured last night, lying in a pool of blood in front of her apartment at 2361 Union Street. Patrolmen at Central Emergency Hospital said Mrs. Thompson named her husband, John Thompson, a chiropractor, as responsible, but later retracted the charge. . . . Officers who took Thompson into custody declared he had been drinking and announced that he would be held on charges of assault with intent to do great bodily harm, and intoxication. Thompson asserted his wife had "fallen out of bed." (San Francisco *Examiner*, February 21, 1937.)

(Continued on Next Page)

NOW YOU CAN PRESCRIBE HEARING AIDS, DOCTOR, WITH THE NEW AUROGAUGE!

Experience has shown that the only answer to the question—"which hearing aid" is the result obtained with a specific aid by a particular individual.

With this fact in mind, engineers in the Acousticon Laboratories have spent eight years in research to evolve a practical device that would permit a deafened or hard-of-hearing person to try quickly and comfortably all of the 960 different ACOUSTICON combinations available.

The procedure is simple—convenient and absolutely accurate. You merely sit before the AUROGAUGE and, by trial and elimination, select the precise combination that gives your patient hearing results. The fitting takes but a few minutes. You are the one who prescribes.

We shall be glad to show you the new AUROGAUGE without obligation on your part. This is not an audiometer.

SMOKING ADVICE THAT'S EASY TO FOLLOW

THE surest way to make a patient follow the doctor's advice is to make that advice easy to follow.

It is not easy to follow the advice, "Stop smoking." But today there is a pleasant alternative: "Smoke only Philip Morris, the one cigarette proved* less irritating."

Ordinary cigarettes use glycerine, now known to be a definite source of irritation. In Philip Morris, diethylene glycol is used exclusively as the hygroscopic agent.

For your own satisfaction we suggest that you test Philip Morris yourself and on your smoking patients.

WHEATON, ILLINOIS

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

"Two members of the asserted coast-wide illegal operations syndicate uncovered last summer were freed on bail from the county jail in an unexpected action yesterday by the Appellate Court. Over protests of the Attorney-General's office, Valentine St. John and James Beggs were allowed to obtain their freedom on \$3,000 bail each, pending outcome of their appeals. Deputy Attorney-General Bayard Rhone protested the action. 'Bail never has been granted on such conditions before,' Rhone said. Convicted on five counts of conspiracy and performing illegal operations, the pair were serving sentences of ten to twenty-five years. Last week they were deprived of their licenses to practice by the State Board of Medical Examiners." (*Los Angeles Times*, February 16, 1937.)

The Effect of Benzedrine Sulfate on Intelligence Scores.—Sargant and Blackburn (*Lancet*, London, 2: 1385, Dec. 12, 1936), conducted an investigation to determine whether the increased confidence and mental alertness reported after the use of "Benzedrine Sulfate" (benzyl methyl carbinamine sulfate) would be accompanied by any real improvement in general mental efficiency as shown by psychometric tests.

After administration of 20 milligrams of "Benzedrine Sulfate," Cattell's "intelligence tests" were given. The results showed the increase in score of over 8 per cent as compared with previous tests without "Benzedrine." The score of a control group receiving placebos remained unchanged.

Individual examinations showed that "Benzedrine" has more effect on mildly depressed cases than on schizophrenics where personality changes are more profound. Even better results might have been obtained if the dosage had been graded to each patient's requirements.

The authors suggest that the drug may prove useful in certain cases where mental efficiency is temporarily impaired by emotion, anxiety, or mild depression.

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

**Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack
and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.**

Zera E. Bolin, M.D., 490 Post Street, San Francisco, California. ✓ ✓ ✓

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermann, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

Mailing containers sent on request. Special delivery postage insures prompt, accurate service.

Tongue Cancer.—According to M. J. Holmes, M.D., the facts about carcinoma of the tongue are:

1. Glandular metastases are the cause of death in the overwhelming proportion of cases at the present time.

2. There is no evidence that radiation therapy can prevent or cure these glandular metastases.

3. There is abundant evidence that surgical excision, properly performed, can in a definite proportion of cases (a) prevent the occurrence of glandular metastases, (b) cure glandular metastases according to their extent and fixity.

4. A surgical excision can cure primary lesions in the tongue when the principles of cancer surgery can be followed; but if the anatomical situation is such that these principles cannot be carried out, and to avoid mutilation even if they can, we must rely upon the selective destructive effects of radium for a cure of the primary growth.

5. It seems that in appropriate dosage radium is capable of producing a remarkable disappearance of outward signs of carcinoma of the tongue in situations where surgical excision cannot be contemplated.—*Medical Journal of Australia*, August 15, 1936.

What Price Recreation.—And one has only to look at the hollow-eyed, body-blistered, head-cold infected men and women limping back from week-ends and vacations to realize fully what atrocities against mental and physical health are self-inflicted under the guise of recreation. The head of a large business firm told me that he dreaded the vacation season each year because of the heavy toll of illnesses that always followed for weeks afterward among his employees, to say nothing of their reduced mental efficiency and lowered morale. It is well that we think a bit seriously about this business of refreshing ourselves in this period of our history when shorter working hours give greater leisure. Do we know how to spend them to the best advantage? What price Recreation!—*Esther Loring Richards, M. D.*

POST- OPERATIVE NAUSEA—

—the “thorn in the flesh” in the use of ether, the safest, simplest, most practical general anesthetic yet known to the medical world, has been removed by the

King THERMANESTER

The King Thermanester makes possible the complete volatilization of ether—thus eliminating all the common post-operative after-effects heretofore associated with its use. Its cost is small . . . operation simple . . . economical in use! Phone or write today for literature or a demonstration.

The said corporation shall have the power to sell said property and to invest and reinvest the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

* These Bequest Forms were discussed editorially in CALIFORNIA AND WESTERN MEDICINE, for March, 1936, p. 145, and June, 1936, p. 460.

Scrambled train orders invite disaster. So in railroading as little as possible is left to memory. Train orders must be written!

Word-of-mouth prescriptions for vitamin products invite trouble, too. If confused or forgotten, the patient may get on the wrong track by selecting a deficient product. And because appearance, taste, smell or weight cannot help the patient to select wisely, low price may decide the choice instead of what matters—certainty of full vitamin content.

That is why many physicians make it a practice to write all their prescriptions for Haliver Oil with Viosterol, and to specify ABBOTT whenever vitamins A and D are indicated. In this way physicians can be

sure that their patients will receive all those vitamin units they prescribed for them.

Abbott's complete control throughout production makes certain that only highest quality fish oil is used. Abbott's rigid bioassays assure vitamin content true to label claims. Another very important assurance of quality is Abbott Laboratories' unique background of original research and manufacturing experience in the vitamin field.

Prescribe routinely for pregnant or lactating mothers, for children and any others who may need additional vitamins A and D. Available at prescription pharmacies everywhere in 3-minim capsules in boxes of 25, 50, 100 and 250. Also in 10-cc., 20-cc. and 50-cc. vials.

Advertisements.—The Journal is published on the seventh of the month. Advertising copy must be received not later than the fifteenth of the month preceding issue. Advertising rates will be sent on request.

BUSINESS MANAGER . FREDERICK C. WARNSHUIS

Advertising Representative for Northern California
L. J. FLYNN, 544 Market Street, San Francisco (DOuglas 0577)

Copyright, 1937, by the California Medical Association.

Subscription prices, \$5 (\$6 for foreign countries); single copies, 50 cents.

Volumes begin with the first of January and the first of July. Subscriptions may commence at any time.

Change of Address.—Request for change of address should give both the old and the new address. No change in any address on the mailing list will be made until such change is requested by county secretaries or by the member concerned.

Responsibility for Statements and Conclusions in Original Articles.—Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. It is aimed to permit authors to have as wide latitude as the general policy of the Journal and the demands on its space may permit. The right to reduce or reject any article is always reserved.

Contributions—Exclusive Publication.—Articles are accepted for publication on condition that they are contributed solely to this Journal. New copy must be sent to the editorial office not later than the fifteenth day of the month preceding the date of publication.

Contributions—Length of Articles; Extra Costs.—Original articles should not exceed three and one-half pages in length. Authors who wish articles of greater length printed must pay extra costs involved. Illustrations in excess of amount allowed by the Council are also extra.

Leaflet Regarding Rules of Publication.—CALIFORNIA AND WESTERN MEDICINE has prepared a leaflet explaining its rules regarding publication. This leaflet gives suggestions on the preparation of manuscripts and of illustrations. It is suggested that contributors to this Journal write to its office requesting a copy of this leaflet.

SOME OF THE LEGISLATION PROPOSED AT SACRAMENTO

Two Hundred and Fifty Proposed Laws Are Related to the Public Health.—An examination of the more than 4,000 proposed laws introduced at Sacramento in January, during the first part of the fifty-second legislative session, shows that about 250 have a direct bearing on public health and medical practice. For the information of members of the California Medical Association, the list compiled by the Association's Committee on Public Policy and Legislation is printed in this issue, on page 205.

Every member of the California Medical Association, therefore, owes it to himself, as citizen and as physician, to take time to glance through that index of suggested legal enactments, some of which—if they went on to passage—would work havoc to the interests of both public and the medical profession. No doctor of medicine, indeed, need feel above doing this, for if he seriously thinks that he lowers the dignity of himself or that of his profession by acknowledging a live interest in proposed laws such as might create great and detrimental changes in his own practice, and that of his colleagues, he certainly may be accused of having a distorted point of view.

* * *

A Heavy Price Is Paid for Indifference in Legislative Matters.—It is true that the successful practice of medicine—in which, from the beginning of the art, so much has always depended upon the confidential and trustful physician-patient relationship—prevents the acceptance by physicians who are in active practice of full-time civil positions and responsibilities; but this fact does not imply that medical men must stand aloof from active observance of legislation affecting medical practice or the public health. It may be said, on the contrary, that in the quiescent attitude of doctors in the past (or, shall we even say their indifference?) is to be found a partial explanation of some of the radical socialized-medicine propaganda which have been so much in evidence in the last several years.

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column which follows.

Absence of Medical Men in the Legislature.—Therefore, it may be in order to call attention to the complexion of the present California Legislature, a roster of whose Senate and Assembly members is given on page 208, disclosing somewhat of these interesting facts:

The Senate, composed of forty members, contains twenty-five Republicans and fifteen Democrats. With respect to occupation, it has sixteen farmers, twelve attorneys, five real estate and insurance agents, three publishers, three merchants, and one druggist. In the reapportionment several years ago, the plan adopted gave almost every county one senator—although for some of the smaller counties it was necessary to effect a grouping. The balance of power in the Senate, therefore, is largely in the counties of lesser population, or the so-called "rural counties."

The Assembly, made up of eighty representatives, includes forty-six Democrats, thirty-three Republicans and one member elected by "write in" process; and respecting occupation, it has thirty-four attorneys, fourteen real estate and insurance agents, thirteen retail business men, seven farmers, five teachers, three labor leaders, three civil engineers, and one publisher. In the Assembly, the metropolitan areas and cities have a majority of votes.

In the above summary it will be noted that while twelve of the forty senators are attorneys, and thirty-four of the eighty assemblymen belong to the legal profession, there is not a single physician in either the upper or lower chamber! It is unfortunate that such is the fact, because the presence of several physicians on the Senate and Assembly floors could be of real value in bringing about the enactment of sane public-health legislation.

* * *

Medical Practice Codification, Medical and Hospital Service Bills.—In the January issue, special mention was made of the codification of the Medical Practice Act, a proposed law providing for the creation of medical service associations, and an act providing for the regulation and control of corporations organized for the purpose of operating nonprofit hospital service plans. These three measures continue to receive the close scrutiny and supervision of the California Medical Association Committee on Public Policy and Legislation, and component county societies will be promptly informed if complications arise.

Apropos of the Williams bill for medical and hospital services to be rendered on an insurance basis, readers are referred to comments made by Chester H. Rowell in the San Francisco *Chronicle* discussing the act sponsored by Senator Williams. These comments are reprinted in this issue, on page 212.

* * *

Law for Registration of Nurses.—At the February 20 meeting of the State Board of Health (which, under the existing law, has the responsibility of supervising schools of nursing and the registration of nurses) that body went on record as being opposed to Assembly Bill 2125, which would exempt certain schools of nursing from the

provisions of the present law, when "such school of nursing is conducted by a university or college in the State of California . . ." The members were unanimous in their opinion that the minimum standards laid down for schools of nursing should be complied with by all schools in the State, and that no exemption from the existing laws concerning schools of nursing and registration of nurses should be granted, even to universities and colleges.

* * *

Optometric Amendments.—The optometrists, in Assembly Bills 1137 to 1142, propose amendments to the Optometric Act which could seriously embarrass physicians and surgeons who are eye specialists. The opticians who grind lenses would be brought under the jurisdiction of the Optometric Board; but why, is not stated. Also, paragraph 3042 in Assembly Bill 1137 states: "The provisions of this chapter do not prevent a duly licensed . . . optometrist from *treating* or fitting human glasses to the eye . . ." Phraseology, such as this, with implied legal right to "treat" eyes, will need careful consideration.

* * *

Supervision of Persons on Entering the State. The public-health menace, in some of the indigent and other camps in California, was discussed editorially in the January number of CALIFORNIA AND WESTERN MEDICINE. So serious has this evil become, that the State Board of Health, in Assembly Bill No. 2115 (Redwine), has asked the Legislature to enact a law that would permit the Board to establish a Division of Health Inspection, with power to inspect all persons entering this State, to determine their condition of health. At the present time, the State is powerless to combat the entrance of persons who are both indigent and diseased.*

* * *

Component County Societies to Work Through the California Medical Association Committee on Public Policy and Legislation.—To comment on all the 250 proposed laws relating to medical practice and the public health would require one or two entire numbers of CALIFORNIA AND WESTERN MEDICINE. It is hoped, therefore, that the brief survey and lists of measures, with their reference numbers as Assembly or Senate bills, as given in this issue,† will demonstrate to members of the California Medical Association that the Committee on Public Policy and Legislation again has a large task on its hands. Officers of component county societies are requested to be alert and, when called upon for service, to be promptly up and doing; but, as before stated, always to act in conjunction with and through the California Medical Association Committee on Public Policy and Legislation.

Members who wish to read the text of certain bills may obtain copies by sending their request (with bill numbers) to the California State Printing Office, Sacramento.

* See also Opinion of the State's Attorney General, on page 177.

† For list of proposed laws, see page 205.

WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION

Remarkable Growth and Record of the California Auxiliary.—The thought has not infrequently come to us: How many of the 5,500 members of the California Medical Association appreciate the growth and good work of the Woman's Auxiliary to the Medical Association? For those who have not watched its development, a perusal of the letters of county units which make up the Auxiliary, and which appear in each issue of CALIFORNIA AND WESTERN MEDICINE, cannot do otherwise than instill an increased pride in the educational and other work which these organized groups of women—the wives and daughters of physicians—have so consistently and efficiently carried on since the founding of the Auxiliary in May, 1929—a brief eight years ago.

The national woman's auxiliary came into being in 1922, but it was not until the Sacramento meeting of the California Medical Association in 1928 that members of the California Medical Association Council were ready to authorize the movement for California. At the Council meeting of April 30, 1928, on our motion, a committee was appointed to bring in a report for submittal to the House of Delegates, and the minutes of the May 2, 1928, meeting of the House include the following item:

(d) *Woman's Auxiliary.*—The Reference Committee approves the recommendation of the Council that a Woman's Auxiliary be formulated in California as it exists in the majority of states.

At the Council meeting of June 1, 1928, the subject was again discussed, the minutes stating:

On motion of Doctor Gibbons, duly seconded, it was

Resolved, That a committee be appointed to present a plan for the formation of the Woman's Auxiliary in California for consideration at the next meeting of the Executive Committee. . . .

Chairman Hamlin appointed George H. Kress (chairman), Edward M. Pallette, and Hartley F. Peart as members of the committee.

Again, in the minutes of the California Medical Association Executive Committee meeting of August 11, 1928, it is recorded:

Woman's Auxiliary.—George H. Kress, chairman of the committee on plans for the organization of the Woman's Auxiliary in California, presented proposed rules for the information of the committee. It was decided that the wives and adult sisters and daughters alone should constitute the active members.

Later, a letter of transmittal was sent to the component county medical societies, with copies of the by-laws or rules to be used in the organization of county auxiliaries, and also a letter outlining a simple procedure for initial organization. It was in this manner that the first county auxiliaries came into being, the State Auxiliary being formed in the spring of 1929.

* * *

California Woman's Auxiliary of 1937.—Today, as noted in the front section directory of each issue of CALIFORNIA AND WESTERN MEDICINE, local auxiliaries exist in the counties of Alameda, Contra Costa, Fresno, Kern, Lassen-Plumas-Modoc, Los Angeles, Marin, Orange, Riverside,

Sacramento, San Diego, San Francisco, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, and Siskiyou.

For proof that these are not "paper societies," but units of alert women, anxious to aid in the promotion of the public health, and of scientific and organized medicine, one need only occasionally read their reports, as printed each month in the OFFICIAL JOURNAL.

As time goes on, we are more and more impressed with the real value of the county auxiliaries, and also that component county medical societies, which have not taken steps to organize such units, may well ask themselves why they do not do so? Officers of county medical societies need do nothing more than write to the State Auxiliary officers to secure sympathetic and efficient coöperation. A Woman's Auxiliary to every County Medical Society would mean stronger component county units, and a greater and more efficient State Association.

* * *

Two Excerpts from the Los Angeles Auxiliary Year Book: Worth Reading.—Before leaving this subject we would present two excerpts from the impressive 1935-1936 year book of the Woman's Auxiliary to the Los Angeles County Medical Association, a volume of forty-four pages, the first quotation touching on the objects of the Auxiliary:

CLUB POLICIES

1. Our aim is to assist in the advancement of the prevention of disease. Health education.
2. To secure better legislation indicated in the pursuance of these ends.
3. To extend the aid of the medical profession to all organizations that look to the advancement of public health conditions.
4. To promote acquaintanceship among physicians' families, and bring about unity and friendliness.
5. Philanthropic—give community service whenever such service is needed, particularly service related to the medical profession.
6. To assist in entertainments at all medical conventions.

Are not the above most laudable aims? Let it be remembered, in connection therewith, that many of the present-day problems having a relationship to economic and allied phases of so-called socialized medicine have come into being because, in the past, physicians failed to sense the importance of maintaining proper educational contacts with lay organizations; where, only too often, biased and visionary propagandists, through addresses teeming with inaccuracies and wild theories, have led substantial citizens, both men and women, astray, by the use of high-sounding phrases, containing only minor substance of little worth.

We close these comments with a second excerpt, showing the fine spirit our wives and daughters hold for their own fellows in auxiliary service, to be found on the dedication page of the 1936-1937 Los Angeles Year Book, inscribed to the retiring president, Mrs. John Vincent Barrow:

TO DOLORES M. BARROW

For her long and loyal service in the Auxiliary,
For her early understanding and enthusiasm during its formative years, both as county director and as State councilor,

For her fine record through two administrations as a State vice-president in broadening the Auxiliary's scope of interest and increasing its field of services,

For her leadership during two and a half years as county president, when she built the membership to the largest county group in the country,

For the joy she finds in her work,

For the inspiration she carries to others,

For her fearless pioneering spirit,

For the trueness of her friendship,

We, the members of the Los Angeles County Medical Auxiliary, dedicate this, the 1936 edition of our year-book.

After consideration of what the California State and County Auxiliaries have accomplished in eight brief years, must we not agree that all members of the California Medical Association may well be proud of the Auxiliaries, and the loyal women who make up the membership and carry on the work of these accessory units so efficient to scientific and organized medicine?

ARMY MEDICAL LIBRARY

The Army Medical Library of Washington, D. C.—Far out as we are, on the Pacific Coast, we may be pardoned if, at times, we seem to forget the immense service rendered by some of the medical institutions and activities headquartered along the Atlantic seaboard. Not the least among these is the Army Medical Library, located at Seventh Street and Independence Avenue, S. W., Washington, D. C., which will become, it is hoped, in the not far distant future, an adjunct of the Army's Walter Reed Hospital of that city.

* * *

Tribute to Army Medical Library by the Late William H. Welch.—It was of this library that the late William H. Welch of Johns Hopkins said:

I have been asked on more than one occasion what have been the really great contributions of this country to medical knowledge. I have given the subject some thought, and think that four should be named:

1. The discovery of anesthesia.
2. The discovery of insect transmission of disease.
3. The development of the modern public health laboratory, in all that the term implies.
4. The Army Medical Library and its Index-Catalogue; and this library and its catalogue are *the most important* of the four.

The Army Medical Library's bigness is shown in its possession of more than one million volumes or items, and of some 450 of the 600 volumes printed prior to or shortly after the year 1500. The oldest of these medical incunabula in the Army Medical Library is Johannes Gerson's *De pollutione nocturna*, from a Cologne press under date of 1467.

* * *

The Late Colonel John Shaw Billings.—In 1936 the Army Medical Library—known up to some fifteen years ago as the Library of the Surgeon-General's office—was one hundred years old. In its growth, it owed its greatest development to the late Colonel John Shaw Billings, a graduate of the Medical Schools of the Uni-

versity of Cincinnati (Miami-Medical College of Ohio), who, as early as 1876, outlined the type and scope of the *Index-Catalogue*, destined to appear, between 1880 and 1895, in sixteen large quarto volumes. In 1879, a monthly catalogue, the *Index Medicus*, was brought off the press by Billings, but the publication, maintained for a while by private subscription, was not able to survive; and in 1899 efforts were made to have the Carnegie Foundation take over its production. This was accomplished, for the period 1903-1927, when again a new sponsor was found in the American Medical Association, which merged it with its own *Quarterly Cumulative Index*, established in 1916, making it the *Quarterly Cumulative Index Medicus*.

* * *

The Largest Medical Library in the World. The Army Medical Library of the United States has the largest collection of medical books in the world, and the service it has rendered to American and World Medicine is hard to estimate. Its worth is splendidly attested in a tribute from the late William Osler, who, as long ago as 1912, wrote: "Probably few men in the profession owe a deeper debt of gratitude to the Surgeon-General's Library than I." As part of the Library's activities, it maintains the Army Medical Museum, also the largest of its kind anywhere.

It is well for California physicians to keep the Army Medical Library in mind, because it extends its facilities to the medical libraries of the State, and, through them, to the physicians of California.

* * *

Army Medical Library Worthy of Congressional Appropriations.—The record of great achievement by the Army Medical Library makes it proper for component county societies to inform the United States Senators and Congressmen from California* that the physicians of the Golden State are in full sympathy with the proposed annual federal appropriations, to provide adequately not only for additions to the volumes already in the Library and give full support to the *Index-Catalogue*, but also to make ample provision for adequate housing in the proposed building to be erected on the new site adjacent to the Walter Reed Hospital in Washington.

THE QUESTION—CAN A CORPORATION PRACTICE MEDICINE IN CALIFORNIA?: THE STATE'S ANSWER TO THE CORPORATION'S APPEAL TO THE CALIFORNIA SUPREME COURT

An Interesting and Important Brief.—On February 4, 1937, the Hon. U. S. Webb, Attorney-General of the State of California, and Lionel Browne, Deputy Attorney-General, as legal representatives for the Respondent (The People of the State of California, *ex rel.*, State Board of Medical Examiners), filed their brief in the appeal

*For list of United States Congressmen from California, see page 208.

taken by the Pacific Health Corporation from the judgment of the Superior Court of the State of California, in and for the County of San Francisco—Hon. C. J. Goodell, Judge,* presenting, as their viewpoint of the issue before the Supreme Court, the following:

THE ISSUE

Was the court correct in determining that the appellant corporation [Pacific Health Corporation] was engaged in the practice of medicine where it paid commissions to solicitors who secured applications for contracts, which, if accepted by appellant [Pacific Health Corporation], permitted the contract holder to secure medical or surgical services from licensed physicians chosen and compensated by appellant corporation [Pacific Health Corporation], or can a corporation undertake to supply medical services through licensed persons chosen and compensated by it, or is it, in so doing, wrongfully engaged in the practice of medicine?

* * *

Points in the Arguments of the Attorneys-General.—In the foreword of the brief, the Attorneys-General state:

FOREWORD

Appellant [Pacific Health Corporation] agrees a corporation cannot legally practice medicine or any other profession, but contends it is not practicing medicine where it undertakes, for a consideration paid by its contract holders, to supply and pay for the services of licensed physicians and surgeons of its choice.

The question before this court, appellant [Pacific Health Corporation] argues, is a social one, and an affirmation of the judgment at bar will outlaw fraternal, religious, hospital, labor union, insurance and other organizations. We [State of California] urge that an affirmation of the judgment herein will do no more than cause appellant [Pacific Health Corporation] to stop doing those things which constitute the practice of medicine, and insist the matters referred to were not before the court below. We believe it advisable to consider those matters which were the subject matter of the agreed statements of fact.

Matters not involved in such statements can be considered if, as, when, and where they arise.

Lack of space prevents giving details of the argument, as outlined in the seventy-six pages needed to impart their understanding of the law of the case, which was analyzed and presented under the following headings:

- I. A Corporation Cannot Practice Medicine
- II. Appellant's False Premise
- III. Rules of Construction Applicable to This Case
- IV. The Statute Defining and Regulating the Practice of Medicine Specifically Prohibits Unlicensed Persons From Engaging in the Acts Which Constitute the Practice of Medicine
- V. The Medical Practice Act Does Not Recognize That a Corporation May Hold Itself Out to the General Public as Supplying Medical Services
- VI. The Medical Practice Act Specifically Prohibits Corporations From Engaging in, Advertising and Holding Itself Out as Being Engaged in the Practice of Medicine
- VII. Appellant was Engaged in the Practice of Medicine Under the Stipulated Facts
- VIII. This Court [California Supreme Court] has Expressly Determined that It Is Illegal for a Corporation to Engage in the Practice of Medi-

cine by Employing Licensed Persons to Treat Persons Having Contracts for Medical Services With the Corporation

- IX. Authorities From Other Jurisdictions Which Permit the Corporate Practice of Medicine Do Not Represent the Law of This State
- X. The Medical Profession's View of the Question at Bar Is Immaterial
- XI. The Medical Practice Act Is Not Violative of the Fourteenth Amendment and Unconstitutional
- XII. The Affirmance of This Judgment Will Not Outlaw Fraternal, Religious, Benevolent and Other Organizations Furnishing Sick Benefits to Their Members

* * *

The Conclusions Presented by the Attorneys-General.—The above notations should be of interest because they indicate the scope and intricacies of such a legal question. Because of its importance to private medical practice, readers may find the following conclusion of the Attorneys-General, as presented in their brief, of real interest:

CONCLUSION

In that portion of its brief denominated "The Law of the Case," the respondent has answered appellant's endeavor to distinguish those cases necessarily dealing with the corporate practice of a profession. The point that a corporation cannot furnish medical services is not here involved. Indeed, under certain circumstances it is the absolute duty of a corporation to provide medical services. Under the Workmen's Compensation Act of this State, a person or corporation employer is required to supply medical attention for their employees, but this is far different than to permit corporations to make money by commercially engaging in the practice of medicine. The people of this State have never urged that a corporation cannot employ attorneys to represent it. It has the same right to employ attorneys to represent it, if it is not doing a law business, as has a natural person.

In the case entitled *In re Benseal et al.*, 124 N. Y. S. 726, it is held that a corporation cannot do indirectly that which it cannot do directly. This case cites *Bronald vs. Engler*, 121 App. Div. 123; 105 N. Y. S. 508, affirmed in 194 N. Y. 323; 87 N. E. 427, 21 L. R. A. (N. S.) 176, which holds:

"Where parties hold themselves out as pursuing the trade of a master plumber, it is a violation of Section 45 of the General Cities Law, Laws of 1900, C. 327, to carry on that business without a license. Persons so doing are not exempt from the condemnation of the statute by the employment of a licensed master plumber as a manager of the business."

It would, therefore, seem that while a corporation may employ a licensed person to render professional services for it—as, for example, to check up on the health of its employees or render first-aid service or the like—it cannot collect money from third persons for rendering services which a licensed person must, under the law, perform.

Wherefore, it is respectfully submitted that the judgment should be affirmed.

Dated: San Francisco, California, February 4, 1937.

U. S. WEBB,

Attorney-General of the State of California.

LIONEL BROWNE,

Deputy Attorney-General of the State of California.

Attorneys for Respondent.

* References in CALIFORNIA AND WESTERN MEDICINE to Judge C. J. Goodell's opinion appeared in the issues of November, 1935 (on page 324) and December, 1935 (on page 397), the full opinion being printed in the December, 1935, number (on page 460). References to other articles on the subject of corporate practice of medicine, and of California Medical Association Council action thereon, were given on page 324 of the November, 1935, issue.

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 187.

EDITORIAL COMMENT†

SCHOOL HEALTH PROGRAMS AND THE MEDICAL PROFESSION*

For the most part, practitioners of medicine and surgery and their specialties have failed to recognize the significance and importance of health programs as being developed in the public schools of this country. School health programs, to a great extent, are associated in the physician's mind with a wish-wash, half-hearted attempt upon the part of school teachers to teach a few health rules such as cleanliness, posture, brushing teeth, etc.

Following are some reasons for this concept:

School health work began many years ago, with few exceptions, as a part of physical education with poorly developed programs. Some less progressive schools continued to have relatively poor programs. Few physicians contact the work directly, because it is carried on within the school department by one or more selected individuals. Physicians, by and large, are incredibly "too busy" to give thought to school health work. An occasional physician feels the school health program is attempting to replace him in his profession in the community. Many physicians are so completely absorbed in their profession, and admirably so, that they are disinclined to find time to contribute to public affairs. School health programs have not been brought to the attention of physicians properly or effectively.

Following is a brief résumé of the functions of a typical school health program:

1. Sanitation. The sanitation of our school children's physical environment, including buildings, grounds, and equipment, is important. Proper sanitary conditions in the schools not only protect the health of the pupils during their school life, but carry over educationally into adult life.

2. Health Service. First aid, health inspections by physicians and nurses, health notices, nurse follow-ups, getting the pupil into the hands of the family physician, communicable disease control, attendance problems, readmission after illness, immunization, skin testing for tuberculosis, nutrition programs, competitive athletic examinations, etc., form the bulk of health service in the schools. Communities differ individually as to methods used in promoting school health service.

3. Health Education. Health education is the most important part of the school health program. It is the fundamental responsibility of the school. It is the very basis of progress in the utilization of the discoveries of medical science to aid mankind. The family physician has difficulty in gaining cooperation with an unintelligent patient. The Public Health Department's efforts to control social and communicable diseases, to promote sani-

tation and preserve community health, are frequently made ineffective by widespread ignorance of the fundamentals of health.

Health education for the masses is developing rapidly through the public schools. Through contacts in the schools of the activities listed under the heading "Health Service," all children, rich and poor, are taught fundamentals of health. Some schools have health teachers specially trained in the field of health information. Many authentic health texts are available for reference work in the schools. The more progressive schools have appropriate health informational materials integrated with all courses of study of the curriculum. Health education is also being taught through special projects and activities of many kinds familiar only to the educator.

The school health program, as a whole, is coming to be an important influence in many communities. It is developing rapidly. It needs guidance and support. It is challenging the attention of the American physician.

How are physicians going to react to this great social and professional influence? The physician pays taxes that support the schools, his own children attend the schools, his work in the field of medicine is affected in some way by it. Is he going to be "too busy" to be interested? Is it not the type of health information taught in the public schools of any importance to him? Will he continue to be "too busy" to help guide and control, or at least be cognizant of one of the greatest influences on his profession in America?

School authorities will welcome suggestions and advice of physicians of good standing in the community. What group could a school department turn to for advice and consideration of its health problems that is better prepared than the physicians themselves? One of the greatest responsibilities of the medical society and the Public Health Department of every community is to give support and guidance to the school administration in the carrying out of a well-organized and adapted school health program.

G. G. WETHERILL,
San Diego.

ADRENALIN CHLORID IN 1:100 STRENGTH IN OPHTHALMOLOGY

John Green,¹ in 1930, first reported upon the use, in fifteen cases, of a solution of adrenalin chlorid, 1:100, in the form of drops in the conjunctival sac. This concentrated solution, which had been supplied him for experimental purposes, was not again used in ophthalmology to the best of our knowledge since that time, and we have found no further mention of it in the literature until June, 1935, when Graeser and Rowe² reported at the meeting of the Association for the Study of Allergy, at Atlantic City, on a new

¹ Green, John: Two Per Cent Epinephrin Solutions as Substitutes for Laevo-Glaucosan. *Arch. Ophth.*, 5:350 (March), 1931.

† This department of CALIFORNIA AND WESTERN MEDICINE presents editorial comment by contributing members on items of medical progress, science and practice, and on topics from recent medical books or journals. An invitation is extended to all members of the California Medical Association to submit brief editorial discussions suitable for publication in this department. No presentation should be over five hundred words in length.

* From the office of the Director Health Education, San Diego City Schools.

method of administering adrenalin chlorid for prompt relief of certain allergic conditions. They found that a 1:100 solution was frequently effective in the relief of bronchial paroxysm. In August, 1935, adrenalin chlorid solution 1:100 was first supplied to the medical profession to be used in the mouth only, for inhalation by means of a glass nebulizer.

It occurred to us that this same adrenalin chlorid preparation could be used as drops in the conjunctival sac; and since December, 1935, we have thus employed it in over one hundred cases with most satisfactory results.

We have found it to be a very effective therapeutic agent in iritis and in glaucoma secondary to uveitis. In has been our impression that exudation was markedly relieved by constriction of the vessels of the iris, and that as a result of this the formation of pupillary membranes, posterior adhesions and blocking of the filtration angle by exudate, with consequent secondary glaucoma, were prevented and relieved.

In our experience adrenalin 1:100 substitutes well for, and from many points of view is preferable to, the present and past methods of applying suprenin products in ophthalmology, such as by subconjunctival injections³ or the placing of wicks⁴ of cotton saturated with a solution of adrenalin chlorid 1:1000, or by the use of concentrated solutions of synthetic epinephrin products, glaucosan⁵ and suprenin bitartrate.⁶ Its further uses and advantages will be reported at a later date in the ophthalmologic journals.

Syphilis Is Preventable.—Syphilis is a disease of civilization and flourishes particularly in communities where there is a massing of individuals. Under such conditions, the opportunities for its spread are very much greater. It depends more upon faulty social conditions than almost any other communicable disease. While prostitution is a tremendous factor in spreading the infection, a very large number of cases are contracted outside of prostitution. It causes more mental and physical suffering than any other known disease. It is preventable and at the present time may be considered as curable. Yet it is doubtful that any other disease can compare with it in the intensity and severity of its onslaughts. Its control is greatly hampered by the attitude of the general public which too often attaches a social stigma to it. Syphilis should be regarded the same as any other infectious disease. The mere fact that it is often venereal in its origin should not hamper its control. Gradually, however, the old idea that it is punishment for sin has become dispelled. Fortunately, a new trend of public opinion can be observed. This has to do with enlightenment, the spreading of knowledge relative to the cause, effects, prevention, and treatment, all of which must be closely bound together in any program for the control of the disease.

CLINICAL PATHOLOGICAL CONFERENCE*

PROCEEDINGS: CORONADO ANNUAL SESSION

Foreword by President Robert A. Peers.—This morning you will notice, from the announcements which have been handed you, that we are departing from the ordinary type of program, and I think it is going to prove excellent. We have with us as an invited guest a man whom many of you know personally, and most of you know by reputation. He is Professor of Medicine at McGill University in Montreal, formerly assistant resident physician at Hopkins under the late Sir William Osler, and also later a Professor of Medicine at the University of Iowa. I feel particularly happy in introducing this speaker because, as perhaps many of you know, I am an ex-Canadian myself. It is a great pleasure to present to you this man from my former homeland, a member of a great race, a representative of a great friendly neighboring country, and a colleague from a great medical school. Ladies and gentlemen, Dr. Campbell P. Howard, Professor of Medicine at McGill University, Montreal, who will take charge of the Clinical-Pathological Conference on this morning's program. Doctor Howard.

REMARKS BY DR. CAMPBELL P. HOWARD

DOCTOR HOWARD: Doctor Peers, I hardly need to say how much I appreciate your kind reference to our sympathy in our homeland. When your Program Committee decided on this adventure, and thought of the Clinical-Pathological Conference, they had to look around for the best-natured clinician available, and someone on the committee knew that I was speaking on the day before and said, "Probably that old fellow, Howard, won't mind holding it." You have to be good-natured to hold a clinical-pathological conference, because what little pride has been left you by previous mistakes is lost at the first autopsy, as you will see presently. I have grown so accustomed to it that I no longer mind and really get as much "kick" as a pathologist does at being wrong. The only thing that I still feel it is my duty to do is to do my best, and after taking or reading a carefully prepared history, both family and personal, and of present illness, having made a complete physical examination, applied all the simple laboratory tests, and called upon my assistants in some of the more elaborate ones, I feel that I am entitled to say that I have done the best that I can. Adding up, then, the results, I feel permitted, as a rule, to come to some pretty definite conclusions. I was taught that it is my duty, or your duty, having done all those things, not to have the point of view that the case should be explored by a friendly or unfriendly surgeon, or a diagnosis made by a friendly or unfriendly pathologist. I do not think

* The Clinical Pathological Conference was held on Tuesday morning, May 26, 1936, at the sixty-fifth annual session of the California Medical Association, May 25 to 28, 1936.

Led by the late Campbell P. Howard, M.D., whose death occurred in Santa Monica, California, on June 3, 1936. (CALIFORNIA AND WESTERN MEDICINE, July, 1936, pages 4 and 102.)

that we are doing our part if we do not make the very best attempt at making a clinical diagnosis, and we insist that our students, interns, and staff write down a diagnosis as soon as the case has been partially studied. First-sight impressions, final clinical diagnosis—and then along comes the pathologist, and very often we disagree. This committee that was appointed to assist me, comprising eight men, pathologically inclined, have asked me to deal kindly with them. I am going to ask them to deal kindly with me. They have chosen very good cases and submitted six for our selection. I picked four of those six. They have drawn up in these little folders an outline, which I am going to read to you, of the case, and, at the end, the autopsy findings. I would ask you not to read the autopsy findings. Had we had time yesterday we would have obliterated from this public list the autopsy findings, so let us play cricket and not look at them. They will be a surprise to us and we will enjoy them much more if we have the surprise later.

CASE I

This first patient (history will be presented pathologically by Doctor Hall), was a white laborer, fifty-five years of age, who entered a hospital on July 25, 1935, complaining of attacks characterized by sudden loss of consciousness; pain in precordial region; shortness of breath on mild exertion; swelling of the feet and ankles. Well, one does not need to be a Sherlock Holmes with those presenting symptoms to have an impression, and I think we are justified in saying right here that that sounds undoubtedly like a cardiovascular syndrome, and our attack in the history taking should be to lay special stress on the family and personal history of cardiovascular disease. I think we are perfectly wise in admitting that.

The family history is uneventful. His own personal history, not taking that in quite the order submitted, is important, because he has been a heavy worker all his life, a day-laborer, earning his bread by the sweat of his brow. He has used alcohol and tobacco very moderately. I do not believe that is of either negative or positive importance. Being a user of both in moderation, I do not think they play very much of a rôle in the etiology of most diseases. More important than that, certainly, is a story of one severe previous illness which was diagnosed as blood poisoning; we will call it septicemia of some sort. It followed an injury to his leg. It may have been septical pyemia. That occurred in 1917, and may have left its mark on the cardiovascular tree, as we know, myocardial, possibly endocardial, and certainly arterial. The pneumonia for two months in 1922 is hardly a significant note. There is no history of a primary sore. The gonorrhea of 1925 is too distant to be significant.

Nine months before entry to the hospital, he noticed moderate loss of strength and endurance, a mild degree of nausea, and lack of his usual feeling of good health. He was given treatment and his condition improved, and he returned to work as a laborer. Three months ago he noticed

shortness of breath on exertion, swelling of the feet and ankles, and felt unable to continue work. At this time, while at home, he suddenly became dizzy, lost consciousness, and was unconscious for a period of about forty-five minutes. He rested at home, was fairly comfortable, but continued to have shortness of breath on exertion. Three days and one day before entry he had attacks of unconsciousness lasting about a half-hour, followed by severe pain in the precordium, the neck and the left arm, and profuse perspiration, with cold, clammy skin. On entry he complained of these pains; severe headache and stiffness of the legs.

These attacks of loss of consciousness naturally arrest one's attention for a moment. He had three such attacks. What, in a cardiovascular history such as this, do they signify? Naturally, some cerebral accident, and from experience of my own I think I could say small hemorrhages, perivascular hemorrhages, following a spasm of one of the cerebral arteries, associated with the diapedesis of red cells, giving an injury which lasted but a short time. These later attacks, associated with Traunley's syndrome, are still more significant, and suggest another angiospasm in another region, coronary. So that cerebral angiospasm, coronary angiospasm, with interference with function of the brain and with further interference with function of the heart, are important points in that history. If I had to make a diagnosis at this stage, I would say that in a laborer of fifty-five we are dealing with arteriosclerotic heart disease, cerebral arteriosclerosis, coronary arteriosclerosis, but he might be a hypertensive. He is on the borderline, as far as age is concerned; but he is a laborer and we see more cases of arteriosclerotic heart disease among the laborers than we do of hypertensive cardiovascular.

Doctor Hall reports that, at physical examination, the patient's temperature was normal; his pulse was only 72, his respirations were 20, and he weighed 170 pounds. The blood pressure, on admission, was recorded as 160/110. General routine physical examination revealed a strongly built man, large frame, and powerful muscles. Poor dental hygiene. The heart was enlarged to the left, and there was a moderately loud systolic murmur at the apex. Pigmented scars over the anterior tibial surfaces—a laborer—so he was entitled to them. The reflexes were normal. The urine was negative, except for an occasional hyaline cast. There were no blood cells. The blood count was, to all intents and purposes, normal. Hemoglobin was 80 per cent, 4,500,000 reds, with normal leukocytes. His blood Wassermann was negative, so syphilitic heart disease, I should say hypertensive heart disease, is ruled out. My pathological friends may not agree, but I am not looking at the anatomical diagnosis now; I have forgotten it.

The electrocardiogram indicated coronary disease, and subsequent records taken during the next ten days confirmed this interpretation.

During the first five days in the hospital he complained of much pain in the precordium, neck, and both arms, but more severe in the left. Narcotics relieved the pain. Blood pressure rose to

180/70 (your printed report states it fell, which is evidently an error), and temperature remained normal. He continued to have occasional attacks of pain, but his condition improved gradually. Electrocardiogram tracings still presented evidence of coronary thrombosis.

I cannot accept that. I have never seen a case of coronary thrombosis with a blood pressure, whether it had risen or fallen, of 180/70. Everything is possible, of course, in medicine, but speaking from experience—for one has to speak from experience—that is not evidence of coronary thrombosis. I do not care what the electrocardiogram will show. I am old-fashioned enough, too well trained by Osler, to accept any laboratory dictum. I should not get annoyed about it, but if I am going to get annoyed about anything it is that—to have some smart alec come in and tell me that man has coronary thrombosis. I call it vigilance. (Laughter.) Mind you, I want electrocardiograms; I ask for as many electrocardiograms as anybody does, and I want the expert to say what he thinks; but that report goes into the positive column only through the negative column, just as the positive Wassermann or the negative Wassermann, the albumin urine, or what not. It is not a positive finding like tubercle bacilli in the sputum or typhoid bacilli in the blood, etc. It is a clinical finding of great importance, but I do not believe, and I ask you to think about it in the future, that it should be taken too seriously. Now, the electrocardiogram reported coronary thrombosis. The man had no fever, one of the symptoms of it. The leukocytes are not given at any particular time, but we are told that at one time they were 8,200. He had no leukocytosis. His blood pressure remained at a level of 180/70. No pericardial friction rub was heard. We do not expect that in more than 25 or 30 per cent of the cases. But that does not sound to me like coronary thrombosis. It sounds to me like hardening of the arteries disease, with angina and possibly a persistent angina, almost the status anginosus of Clifford Orbutt. These are the remarks I have to make about the case at this stage.

When he had been in the hospital about nine weeks, more interesting things developed. First, a low-grade fever, fluctuating between 99 and 101 degrees, and the pulse rate rose to 100. You recall his admission pulse rate was 72. The precordial pain had practically disappeared; of course, that would happen even in coronary thrombosis by this time. He developed, however, transient redness, swelling, pain, and tenderness in various joints of the extremities. I would like you to remember that, because I am going to refer to it in a moment. He developed an arthritis, or an arthralgia. His appetite became poor, he lost weight, his temperature became higher, a leukocytosis developed (18,000), the hemoglobin dropped to 60 per cent, and a blood culture on October 28 revealed *Streptococcus viridans*. And now we know that the patient has a septicemia due to the *Streptococcus viridans*, the organism so quickly associated with subacute bacterial endocarditis. Looking back to that development of fever, malaise,

loss of weight, and leukocytosis, plus the arthralgic symptoms, I could say at this point, if the case were mine, that this man has developed on top of an arteriosclerotic heart a subacute bacterial endocarditis, and his days are numbered. Blood and albumin appeared in the urine, whereas on admission they had been negative. Profuse perspiration, great loss of weight, and weakness developed. Acute pain, note, in the left upper quadrant of the abdomen, later in the right lower quadrant. Blood and albumin were found in the urine. With these episodes, which were of two to five days' duration, there was marked tenderness, but practically no increased rigidity over the abdominal wall in the region of the spleen or elsewhere. The systolic murmur at the apex did not change. During December, petechiae developed, not only in the skin but in the mucous membranes of the mouth and in the conjunctivae. We have the whole picture of subacute bacterial endocarditis, as first called to our attention by Manuel Lipman of Mount Sinai Hospital many years ago, and now a well-recognized clinical condition, just as well recognized as typhoid fever or tuberculosis.

He became semicomatose, developed signs of pneumonia, and died January 20, 1936, greatly emaciated, very anemic, and exhausted.

The diagnosis on entry, the report states, was hypertension, cardiac hypertrophy, and coronary thrombosis. Hypertension at 160? No! I disagree. That is not essential hypertension. That is the hypertension secondary to arteriosclerosis. Cardiac hypertrophy, yes; coronary thrombosis, no.

Then the final diagnosis of subacute bacterial endocarditis was made. It had been suggested that, since the heart murmur was only an apical systolic murmur and did not change throughout the course of the disease, there may have developed a mural thrombus in the heart which resulted from the coronary thrombosis which was suspected; a very plausible explanation—a very nice explanation. I agree with that, and say it was very smart, a good idea with the diagnosis of coronary thrombosis.

The terminal bronchopneumonia, the infarcts of the spleen and kidneys are of no great interest. The terminal bronchopneumonia is a terminal event in every acutely febrile case, and the infarction of the spleen and kidney is part and parcel to subacute bacterial endocarditis.

Now, ladies and gentlemen, we will hear what our friends, the pathologists, have to say, and I know that you do not need to tell them not to spare me or my blushes.

Report of the Pathologists:

DOCTOR HALL: Doctor Peers, Doctor Howard, Members of the Society: I am sure we shall not let Doctor Howard down very severely in this case.

. . . Doctor Hall reads autopsy report. . . .

COMMENT

DOCTOR HOWARD: I think you will agree we got off rather easily that time. I feel that the explanation for every symptom was there. Every

clinical laboratory finding was there in the autopsy, and the only thing that we have to criticize is the stress that was given to the report of coronary thrombosis by the electrocardiogram. The patient also should not have been considered a hypertensive. We will say more about that in the next case. It is too easily applied. A nurse can be trained to take a blood pressure, and if it is just a question of taking a blood pressure and calling a patient hypertensive, we should go out of business; certainly not spend four to eight years in training. I would suggest to you: never be satisfied with the diagnosis of hypertension and only after mature consideration, weighing the pros and cons, make a diagnosis of essential hypertension. So many other conditions may give rise to an increase in blood pressure of a moderate degree.

* * *

CASE 2

The second case is one that is much more unusual and very instructive.

The patient was a woman whose pathological findings Doctor Maner will discuss. Forty years of age, married seventeen years, and observed at the hospital from March 10 to March 17, 1934. Second admission, March 31 to April 1, 1934. She finally died at home on May 11, 1934.

The family history is negative.

The past history reveals a lot of infections. Scarlet fever is the most important one notoriously in relation to the kidney, and possibly some of you would overstress that from the subsequent developments. Some of you would say that this woman of forty at the age of three had acquired a glomerular nephritis which was eventually responsible for her terminal symptoms. Then so-called "typhoid malaria" at the age of eight; I place it in quotation marks because there is no such animal, as we all know. She had some infection at the age of eight, presumably typhoid. She also had, following this, measles in moderate severity, and then symptoms of frequency of urination, nocturia, and slight edema for several years. She was a multipara, had three children, all in good health. She had three abortions.

The present illness began two years before, coming under observation, with a stroke, causing partial paralysis of the left side of the face, the left arm, and the leg. After a few months she recovered and has since noticed only a slight weakness on that side. The diagnosis at that time was hypertension and nephritis. I have nothing to say to that. Also, of course, we could assume that she had a leak into her vein from an artery, resulting in that partial paralysis of the left side of the body. The systolic blood pressure at that time, two years ago, was only 200. Not marked; it was high. There was some polyuria as also nocturia.

About January 26, 1934, a second stroke occurred, involving this time the right side. She was taken to a hospital, where she remained about two weeks. During that time she had such severe headaches, nausea, and vomiting, that a spinal puncture was done to relieve the intracranial pres-

sure. A little later an osteopathic physician was consulted, and he was a good salesman and told the patient that she was suffering from a syphilitic brain tumor about the size of a walnut (it does not say with the shell on or without—I would like to know) in the posterior portion of the brain, which was pressing on the nerves, causing all her symptoms, *i. e.*, the headache, nausea, vomiting, high blood pressure, nocturia, etc. What is possibly more important is that the spinal fluid Wassermann was three plus.

Now, I would like to stop here. I would have been very much up in the air because here is a woman of forty, with symptoms of cerebral spinal disease and a spinal fluid which was three plus. Of course, it will not explain the hypertension, but one would naturally have to consider cerebrospinal vascular lues.

On March 3, 1934, the patient was brought to the office of another physician for verification of the osteopath's diagnosis. At this time all the symptoms of nausea, vomiting, severe headaches, were more severe, and she was beginning to complain of inability to see clearly, especially in reading. Hospitalization was advised and she entered the hospital again for diagnosis and the relief of her symptoms. At this time she was still fairly well nourished, extremely nervous, apprehensive, no doubt, lying in bed, with no evidence of dyspnea. Temperature was 99 degrees; respiration, 18; pulse, 110, full and bounding; blood pressure, 240/150. I think all agree that a diastolic pressure above 100 is a significant fact, and I think that at this point any one of us would be justified in saying, "Never mind the symptoms for the moment; we are dealing with malignant hypertension, anyway." What do I mean by malignant hypertension? But I know you know much more than two or three of my recent students who, in an examination on malignant hypertension which they were asked to discuss, said, in one case, "I know nothing about it; I have never heard of it." Another said, "I know so little about it, as apparently is true of Lewis, who has devoted only a small paragraph to the subject in his textbook on diseases of the heart." I did not take the trouble to verify that statement. I think it may have been true because Lewis is an electrocardiograph specialist. He is a physiologist and a cardiologist, but he is not a clinician, and he may not think that malignant hypertension is an important question. We in hospitals have to disagree with him. We believe it is a very important question.

Let me remind you that it was many years ago that Gullen Sutton pointed out that the most important thing about any disease was the arterial lesion, and when the sphygmograph was introduced by Bausch in 1893, a clinical instrument of great value was put on the market. The wonderful writings of Clifford Orbutt helped to interest the medical student in the problems of hypertension, and he it was who coined the term "essential hypertension." His two volumes on "Arteriosclerosis and Diseases of the Artery" are still classics. Thanks are due to Bolard and Farre, who pointed out that there was a group of cases which

might be termed truly malignant, and that the majority of cases of essential hypertension were benign. So that we began to think in 1914 of the benign and the malignant nephrosclerosis, those at least who had read Bolard and Farre's monograph. Later Farre suggested that the term "malignant" should be applied most emphatically to this group, and he would add the term "malignant nephrosclerosis," not merely malignant hypertension. His pathologic studies had so impressed him with the fact that the main suffering organ was the kidney that he said, "We will not speak of malignant hypertension alone. We will say malignant nephrosclerosis." Then, later in this country and elsewhere, Keith and Wagoner, studying a large group of cases, stressed even more so this lesion in the kidney described by Bolard and Farre, and even suggested that it is a distinct entity, that it is as much an entity as chronic glomerular nephritis, and that malignant hypertension does not develop merely as a result of essential hypertension of the benign type, but is malignant from the beginning of things. While I am not prepared to agree with that, I want to say that in looking over this history and the clinical findings to date, I would be inclined to regard this case now as malignant nephrosclerosis.

The examination of the patient was otherwise unimportant. The laboratory findings revealed a urine containing two plus albumin, rare hyaline cast, two to three red cells per high power field, and some leukocytes in this centrifugalized sediment. Other urine samples showed a specific gravity ranging from 1.015 to 1.017, an almost fixed specific gravity; no hematuria; no further casts found. So that we have evidence, then, of the malignant sclerotic disease. The blood count showed a slight reduction of the reds and the hemoglobin, a slight leukocytosis, and Wassermann tests were negative, as were Kahn tests. The spinal fluid showed marked increase in pressure, but only three cells. No increase in globulin. The next Wassermann was negative. The report does not say who took that spinal fluid that was sent before. I presume it was done in the hospital and, as often happens, the Wassermann is a false positive. Certainly, the examination subsequently of the spinal fluid rules out cerebrospinal vascular syphilis. The concentration test of the urine showed fixed specific gravity. A contracted kidney followed this. The blood chemistry showed retention of a moderate degree of nonprotein nitrogen. Uremia was impending. The treatment was the classical one of glucose intravenously daily, luminal sedatives, magnesium sulphate, and pancreatic tissue extract. I have never had any experience with that, so I cannot criticize.

The progress of the case was downward. The pulse ranged from 80 to 100; the blood pressure reached 256/190—it never fell below 172/130, and that was after intravenous glucose saline. Nausea and vomiting stopped. During the first few days, the patient was incoherent in speech and disoriented at times and very restless, as these patients nearly always are—apprehensive and restless as can be.

After a week she was allowed to go home. All nausea and vomiting ceased. Two weeks later she reported for another spinal puncture, with relief. The spinal fluid was not under the former high pressure, but the patient experienced marked relief from her headaches, etc.

From April to May 10 she was at home in bed, attended by a private nurse. During that interval she gradually became weaker, had a return of vomiting, and lost the sight of both eyes. No doubt, had a fundus examination been made at this time there would have been an extensive hemorrhagic uoretinitis, which in itself has its peculiar features and is so well recognized that our ophthalmologist often has the temerity to report malignant hypertension, nephrosclerosis, before we have made the diagnosis. Once he hurt our feelings very much in this, but we proved later to be right.

The patient finally died, so the diagnosis seems, to one who knows malignant nephrosclerosis of Bolard and Farre, to be a straight case of malignant nephrosclerosis. There is nothing more to say about it. The course of a few months is the usual one. The disease rarely lasts more than a year. It is to be separated entirely from secondary contracted kidney and from nephritis. It gives many symptoms that simulate the secondary contracted kidney, and very often one finds the condition adhering to that diagnosis in spite of the description of the other condition which I have just given you. We want you to bear that in mind—that there is such a disease as malignant hypertension, usually occurring in women and younger men, running a rapidly progressive course and ending in uremia, rapidly developed in the majority of cases, cardiac failure, or cerebral accident.

Now we are going to hear what the pathologic findings were. Doctor Maner.

Report of the Pathologist:

DOCTOR MANER: I may add that the Wassermann in this particular case that the doctor mentions was done by the osteopath. The necropsy here was performed by Doctor Foord, and was studied and presented by me through his courtesy. . . . Doctor Maner reads his report. . . .

✓ ✓ ✓ CASE 3

DOCTOR HOWARD: Doctor Budd will report on the third case which we selected. This was a young married woman of thirty-four, who had nothing of really great importance in her past medical history; measles, mumps, pertussis, chicken pox, etc. Her tonsils and adenoids were removed in 1921 for frequent sore throat. A severe bronchitis or bronchopneumonia occurred in 1932, from which the patient slowly recovered. There has been an intermittent fever with chills for the past eight years, and a diagnosis of malaria was made at one time. I am going to ask Doctor Budd afterward where she lived, and whether it was possible that she did have malaria at that time. Naturally, anybody remembering the Pel Epstein syndrome occurring in the later stages of Hodgkin's disease,

might think that that malaria-like fever could have been a Pel Epstein syndrome. I have known a case of Hodgkin's disease to last as long as that with a history of Pel Epstein syndrome eight years before, so I am more inclined to think that that intermittent fever with chills was probably a malaria, although it would depend upon the place of residence both in childhood and adolescence. She has had attacks of severe headache intermittently all her life, causing vomiting—migraine, in all probability—and of no interest. The patient has been very emotional, and her hair turned gray prematurely six years ago, at the age of twenty-eight. That is not an uncommon associated phenomenon in my experience with migraine. The family history is irrelevant. She complained, when she was admitted, of enlargement of the spleen, enlargement of the glands, loss of strength, loss of weight and appetite, and jaundice.

The illness dated back to April, 1934, when she first developed a painful lump in the left upper neck. There was a memory of a mild sore throat prior to this. The virus of Hodgkin's disease is usually supposed to enter through the nasal passages. Her general condition remained good until September of the same year, when three enlarged lymph glands were discovered in the left cervical chain. These glands were symptomless, and in February, 1935, one of them was removed for biopsy. The diagnosis reported by the pathologist was Hodgkin's disease. The patient remained in good health and continued to work, although she had a mild anemia and intermittent fever up to 101 degrees.

During March, 1935, high voltage x-ray therapy was given to the enlarged glands in the left neck, mediastinum, and upper peritoneal cavity and to the enlarged spleen. A prompt regression of glands occurred, with improvement in health and a gain of fifteen pounds in weight.

The blood count at this time, we are told, showed slight anemia, 80 per cent hemoglobin, with a leukopenia of 4,300, but that leukopenia was peculiar because, contrary to most leukopenias, the polymorphonuclears were relatively increased—79 per cent. Small lymphocytes were only 11; large lymphocytes, 1; transitional cells, possibly the only significant thing in the differential, 5; eosinophils, 3; and basophils, 1. The picture is one that is quite in keeping with Hodgkin's disease. Its negative Wassermann exists habitually, and the most peculiar thing was the leukopenia with polymorphonuclears in regard to this.

The patient remained well until August, 1935, at which time examination revealed the eyes, nose, and throat to be normal; teeth sound; and chest, heart, and lungs normal. Two indurated glands were found in the right axilla and one in the left axilla. There was an abnormal resistance in the epigastrium from an obvious retroperitoneal mass of undetermined size. The liver and spleen could not be felt. Shotty glands were present in both groins of only suspicious character.

Radiographic studies of the ribs, lungs, and mediastinum failed to reveal any evidence of abnormal pathology.

The blood count then revealed a hemoglobin of 64 per cent, a drop; reds of 4,290,000; whites of 4,900; and no malaria parasites could be found. She had a further x-ray treatment.

The patient remained in good health until the first part of December, when she began to suffer with severe headaches, a fever of 101 degrees, and greatly increased jaundice. That, of course, is an unusual feature, and at once attracts one's attention. I feel certain that we would suspect, as sometimes occurs in so-called abdominal Hodgkin's disease, involvement of a group of glands somewhere near the common duct and pressing on the common duct, and resulting in an obstructive jaundice. Loss of appetite and strength and weight persisted.

The blood count on January 6 showed a further drop, 22 per cent; reds, 1,410,000; and the whites were still lower, 1,500. Differential count showed that same polymorphonuclears predominance, 95, of which 3 were juvenile, 20 stab, and 72 were the ordinary segmented forms; monocytes, 3; plasma cells, 1; and myelocytes, 1. The red cells were of varying size and shape. The average size of the cell was approximately normal. There was a moderate poikilocytosis. There was some polychromatophilia. There was a complete absence of lymphocytes, with a marked left shift in the polymorphonuclears. The platelets were now distinctly reduced in number. Of course, she had had so much x-ray therapy one might very well expect that. My only regret is, from what I have read about the case, that we do not know what the platelets were when she first came under observation. As many of you know, Buerke of Madison, Wisconsin, many years ago, when he was still an assistant in pathology to Welch and Hopkins, found and stressed the frequency of an increased platelet count as a feature of Hodgkin's disease; and we have accepted that at its face value. We do not rule out Hodgkin's when it is not present, but it is very, very frequently present. If I were to have a blood report on the case, as I naturally would like in every case, I would rather have the platelet than anything else. There is nearly always in the early stage, before x-ray therapy or radium therapy has been instituted, an increase in the platelets. The urine was reported as negative except for the urobilin much increased, urobilinogen also increased, and the stool examination was negative.

The patient was finally hospitalized with the hope of controlling the nausea. The blood counts revealed further anemia. The direct Van den Bergh showed an immediate heavy positive; indirect Van den Bergh, 16 units. She was given blood transfusions at weekly intervals without apparent benefit. The stool examination remained normal. On January 25 the blood count was still further reduced: 19 per cent hemoglobin, 880,000 reds, white blood cells 1,400; and there were 9 lymphocytes now. The jaundice was extreme and the patient was irrational. There was marked edema of all the tissues, and the liver and spleen now both reached two fingerbreadths below the costal margin. She died on January 26, 1936.

Of course we had the biopsy, which we should have in every case. If you ever miss Hodgkin's disease it is your own fault, because early in the disease a biopsy should be done. Now to confess the truth, in spite of my knowledge of that, I missed a case of Hodgkin's disease in a young Irish-Canadian woman who was the picture of tuberculosis: the dark swarthy type, with hair on her forearms and legs, emaciated, having glands in the neck, a cough, a mediastinal dullness, and an x-ray plate which showed plainly the mottling of the lung and calcified areas of the tracheo-bronchial type of an early childhood tuberculosis. The clinician told me that she had a positive Von Pirquet of one to ten thousand. She had a little fever, she was sweating, and she had all the symptoms of tuberculosis of the lungs. She was coughing, but no tubercle bacilli could be found. We advised sanitarium treatment, but she did very badly under it. She was sent home by the sanitarium physician, a wise man, saying that this was not tuberculosis; it was Hodgkin's. When she came home we had, then, to my shame, what I should have ordered before, a biopsy, and it was Hodgkin's. She is dying now from Hodgkin's. So, in any suspicious case, as this case well illustrates, a biopsy will make the diagnosis because—as Dorothy Reed McCallum pointed out long ago; Sternberg, too, of course—there is a histologic picture in the glands that occurs in no other condition, whether or not you accept the Dorothy Reed specificity or the Dorothy Reed cell. Whether you accept it or not, there is a combined histologic picture which I think cannot be questioned, and the histologists in this country are perfectly ready to accept it and to make a diagnosis for you early, as early as the gland is submitted. Doctor Foord is going to discuss this case.

Report of the Pathologist:

DOCTOR FOORD: Mr. Chairman, Gentlemen: The interesting thing to me was the profound anemia which came on six months after x-ray was stopped, and in our postmortem I think we can explain some of the causes.

. . . Doctor Foord reads his report.

COMMENT

DOCTOR HOWARD: Now, ladies and gentlemen, we got a surprise there in the finding in the bone marrow. It is, I am sure, clinically a very rare event and also pathologically, as far as my case could go. I recall only one similar case in which the bone marrow was so extensively involved, so our interpretation of the absence of platelets and the low blood count of progressive anemia as due to possible over-x-ray radiation was not justified, and Doctor Foord has given you the explanation in the destruction of the hematopoietic system by invasion of Hodgkin's tissue.

IN CONCLUSION

You have been very kind and considerate, but my time is up and I am going to ask the privilege of calling it a day's work. Doctor Budd had a very interesting case of acute lymphatic leukemia

for us, but as it is half-past twelve and I know you are tired we are going to close the discussion. (Applause.)

• • •

PRESIDENT PEERS: One moment, please. I think your chairman should express his great pleasure at the success of this conference. I think that this innovation, which has been introduced by the Program Committee, has been a wonderful success and it has been due to a number of factors. First, we have had a number of men who have given a great deal of time to the preparation of this program and worked the cases up well and had autopsy reports. Then, in addition to that—and here is a suggestion for any future programs of this sort—we hope that you can get a leader with the great experience and the wide knowledge and keen analytical mind of the gentleman who presided this morning at this conference. If you could get one with the same kindly humor and charming manner of delivery as our friend here, I am sure that the next conference of this sort will be a great success. I thank you, Doctor Howard, and I thank all the members of and leaders in this conference for the splendid work they have done in making such a wonderful success of the morning. Thank you very much. (Applause.)

. . . The meeting was adjourned by President Peers.

PROTAMIN INSULIN: SOME CLINICAL STUDIES

CALCIUM AND ZINC PREPARATIONS WITH INSULIN

By BERTNARD SMITH, M.D.

AND

WILLIAM H. GRISHAW, M.D.

Los Angeles

THE studies comprising this report are a continuation of those previously reported on the use of simple protamin insulin,¹ and are concerned with mixtures of calcium and zinc in the precipitated insulin, including the present zinc series of the more stable mixed form.* A total of 174 patients have been under observation with protamin insulin therapy, and 150 are included in this report. Of these, eighty-eight patients are adults and sixty-two are juveniles, with an age range from 18 months to 79 years. Forty-five patients have been hospitalized for a closer study at the beginning of protamin treatment. Daily urine analyses were made on these patients. Ambulatory patients have been seen once a week, with analyses of urine on each visit. Urines have been routinely collected in two twelve-hour periods to cover the full twenty-four hours immediately before the visit, and the daily analyses for all hospitalized patients have been collected in the same two

* All preparations of protamin insulin used in these studies have been supplied by the Eli Lilly Company, and appreciation is now expressed for the courtesy and generosity this company has shown throughout the work.

All clinic patients selected for this study are from the diabetic services of the Cedars of Lebanon and Children's hospitals. The interest and coöperation shown by the various staffs of these institutions have been of great help.

periods of each day. Blood-sugar tests have been done for certain studies, but these have been no part of the regular routine.

PROTAMIN INSULIN AND INSULIN ABSORPTION

In the studies with simple protamin insulin it was found that the rate of insulin absorption varied with the different patients, and even in the same patient under certain conditions. The same is seen in patients included in this study, and becomes important in the determination of proper time and unit strength of dosage of the present precipitated insulin. This individual problem is the more difficult in those diabetic patients who have been using the regular insulin for some years, and the disturbance to the diabetic control with these patients is often marked immediately after the change to the precipitated protamin insulin.

Of the 150 patients, 113 are grouped as either insulin sensitive or insulin resistant. Identification of these two types appears to be more definite under protamin insulin treatment than under regular insulin. The characteristics of the two groups have been described^{2,3,4} and need not be given in this report. However, the identification of the two groups seems to be of no little importance in protamin insulin therapy in both routine of treatment and in prognosis. Members of the insulin resistant group—insulin wasters⁵—are always severe diabetics, but this is not necessarily true of the sensitive group. The following classification covers the 150 patients:

Severe	79
Moderately severe	63
Mild	8
Insulin sensitive	62
Insulin resistant	51

Some influence from the previous studies with simple protamin insulin may have been carried over into these later studies, and is an explanation of the seemingly routine habit of prescribing two daily doses of protamin insulin. With both the calcium and the zinc mixtures, these injections have been taken at some definite time rather than in relation to meals, as has been usual with regular insulin. No attempt has been made to prescribe routinely both regular insulin and protamin insulin.

For convenience, the abbreviations R-I for regular insulin, and CaP-I and ZP-I for the two preparations of protamin insulin will be used in the text which follows.

THE ADJUSTMENT PERIOD

In beginning P-I treatment, the early weeks must be given to a determination of the individual absorption rate and the problem of timing the dosage to the best advantage of the patient. This adjustment time may take several weeks, and is referred to in the tables as first period. It is important in this adjustment period to make all insulin changes carefully and not too frequently, or a continued loss of diabetic control will result. At the present time only twelve patients are taking both R-I and P-I. Eight of these take a morning injection of R-I, and both morning and evening doses of P-I; two take one dose of R-I in the morning and one of P-I in the evening; two take

one injection each of R-I and P-I in the morning. Six patients continue at present to use CaP-I. These patients are well controlled. The change from CaP-I to ZP-I may cause a high percentage of glycosuria or some disturbing degree of hypoglycemia, and it has been found necessary to make the shift from the calcium mixture to zinc gradually, and with close observation of symptoms and laboratory analyses. With the present zinc preparation that is supplied already mixed, there may be seen occasional loss of diabetic control in changing from one letter series to another, or from one bottle to another in the same letter series. Some considerable part of this loss in control may be due to faulty shaking of the bottle before the insulin dose is withdrawn. The precipitate in the bottle will settle out when the bottle stands upright, and an even distribution will not be obtained if the shaking is faulty.

TABLE 1.—Comparison of Diabetic Control

	R-I Per Cent	First Period. Per Cent	Present. Per Cent
Good	13.6	36.6	64.0
Fair	32.4	36.0	29.4
Poor	54.0	27.4	6.6

COMPARISON OF DIABETIC CONTROL

Table 1 gives a comparison of diabetic control for the entire 150 patients. The term "good" has been used to indicate a loss of sugar of ten grams and less in twenty-four hours. The term "fair" indicates a loss of ten to forty grams. Good to good indicates a good control maintained. Table 2 gives a comparison of control and of insulin dose between R-I and CaP-I, and is based on the eighty patients who began using the calcium mixture.

TABLE 2.—Comparison of Control and Dose

R-I and CaP-I			
Control.	Per Cent	Dose.	Per Cent
Improved ..	52.5	Increased ..	47.4
Unimproved ..	20.0	Same ..	32.6
Worse ..	18.5	Less ..	20.0
Good to good ..	9.0		

INSULIN EFFECT OF PROTAMIN INSULIN WITH CALCIUM PREPARATIONS

The insulin effect of CaP-I is not as prolonged as with the zinc preparation. Some part of the unsatisfactory control shown in Table 2 may be due to this shorter duration of insulin effect. Could the eighty patients have been limited to those who absorbed the precipitated insulin more slowly, the percentage of those showing poor control might have been reduced. A comparative duration effect of insulin from CaP-I and ZP-I is given in Table 3 as blood-sugar analyses. This patient, age forty-four years, required three daily injections of R-I for control. He has remained in good control, with continued sugar-free urines, for nearly six months on one injection of ZP-I a week, and shows a hyperglycemia when the interval between insulin injections is from ten to fourteen days. The case is unusual and the patient will probably require daily doses some time in the future.

TABLE 3.—Duration of Insulin Effect

Blood Sugars Date		CaP-I and ZP-I			
		Time			
	Fasting	9 a.m.	11 a.m.	3 p.m.	
July 23.....	136	138	106	158	July 22. Twenty unit dose of CaP-I given.
July 24.....	135	152	128	163	
July 25.....	148	182	170	200	
July 29.....	154	164	174	136	July 28. One 16 unit dose of ZP-I given.
July 30.....	105	134	121	145	
July 31.....	123	160	148	207	

INSULIN ABSORPTION PROBLEM

Since the degree of diabetic control obtained with protamin insulin depends largely on the rate at which each patient absorbs the insulin, this absorption problem becomes of great importance when the precipitated insulin is given twice daily, and the most favorable time for the two injections can be determined only when the rate of absorption is known. Somewhat routinely in these studies, the interval between morning and evening injections has been twelve hours at the beginning of protamin treatment. The morning dose has usually been taken before breakfast and the evening dose twelve hours later, which is often after the evening meal. On this routine severe hypoglycemic reactions may occur between midnight and breakfast, usually between 3 and 6 a. m. The food plays considerable part in protecting these patients from reaction symptoms during the day, but the usual bedtime food does not give protection throughout the night. These patients appear to be absorbing insulin from the dose of the previous morning, and to be beginning to receive effective insulin from the evening dose as well. This gives an overlapping period from excess insulin during the night. The reaction symptoms may clear entirely by taking the evening insulin one or more hours later, or by reducing the unit strength of the morning injection.

DOSE ARRANGEMENT

In Table 4 is seen the changes in dose arrangement as at present compared with the end of the first period. These changes give some indication of the individual nature of the problem.

TABLE 4.—Changes in Unit Dose Arrangement

	First Period.	Present.
	Per Cent	Per Cent
Larger dose in morning.....	37.4	4.7
Larger dose in evening.....	16.6	27.2
Equal morning and evening doses.....	15.7	24.6
Single dose.....	30.3	43.5

CONTROL AND DOSE COMPARISONS: UNDER
DIFFERENT METHODS

In Table 5, the improvement at present over the condition at the end of the first period is mainly due to an avoidance of frequent changes either in time of injections or unit strength of dose. The changes in time of the injection when two daily doses of protamin have been prescribed more often concerns only the evening dose, since the morning injection time is more or less fixed. After any change in time of dose there must be allowed sufficient period for the patient to adjust to the change before another break in the routine.

TABLE 5.—Comparison of Control and Dose

A. Comparison of End of First Period and Previous Regular Insulin			
Control	Per Cent	Unit Dose	Per Cent
Improved	50.3	Increased	44.9
Unimproved	32.6	Same	38.8
Worse	6.8	Less	16.3
Good to good.....	10.3

Present with Former Regular Insulin		Per Cent
Improved		74.0
Unimproved		11.4
Worse		3.3
Good to good.....		11.3

ADVANTAGES OF LESSER NUMBER OF
INJECTIONS

The fewer injections required daily with the precipitated insulin is of definite advantage to the diabetic patient in school or at work. Such comparison of number of daily doses between regular insulin and present protamin insulin is given in Table 7.

TABLE 7.—Comparison of Number of Injections

Daily	1	2	3	4	4 plus.	Weekly
Regular insulin	6	83	47	13	1	
Protamin insulin	67	82	0	0		1

COMPARISON OF CONTROL: R-I AND PRESENT

A comparison of control of the present with former R-I is given in Table 8, in which the control is shown by a compared unit dosage of insulin. In the classified portion of the table are included the two types of insulin sensitive and insulin resistant. That the insulin resistant type comprises over 50 per cent of the cases that have required an increase in unit dose, gives some idea of their severity and the difficult problems they present.

COMPARISON OF THE NUMBER OF DAILY
INJECTIONS

In Table 9 is shown a comparison of the number of daily injections of R-I and P-I by classified groups. It is seen in this table that many of the insulin sensitive group are able to maintain diabetic control on one injection of protamin insulin daily. With the insulin resistant group this has been true of five patients out of fifty-one. Twelve of the twenty-seven insulin sensitive patients who took two doses daily of P-I at the time the data

PROBLEMS OF SEVERE DIABETICS NOT ALL SOLVED

It is evident from the tables that the problems of the severe diabetic are not all solved at the present time with the new protamin insulin treatment. However, even in the more difficult resistant group, diabetic control has been more satisfactorily maintained than under former regular insulin therapy. It is possible that the experience obtained with long periods of use will improve the routine of protamin insulin treatment, and give a clearer understanding of the more complex problems that enter into the picture of the more severe types of the disease.

JUVENILE DIABETES: STUDIES

Of the sixty-two juvenile diabetics studied, none have diabetes of mild degree. There are thirty-six severe and twenty-six moderately severe cases. Of the severe group, twenty-five are of the insulin resistant type; and of the entire group, thirty-one, or 50 per cent, are insulin sensitive. Thirty-three patients in this juvenile group take two doses of P-I daily, and six of these take regular insulin in addition. Of this group of thirty-three patients, twenty-two are insulin resistant. Twenty-nine of the juvenile cases are on one dose of P-I daily. Of these, three are wasters, one of whom takes a morning dose of R-I and an evening dose of P-I. We are interested in the group of juveniles ten years of age or under, particularly as to their ability to be controlled on one injection of insulin daily. There are twenty-two patients in this age group, and seventeen of these now take a single P-I dose. None of these seventeen cases are listed as insulin resistant, but sixteen are insulin sensitive. The five patients of this group who are on two doses daily are all insulin sensitive.

TABLE 11.—*Comparison of Diabetic Control*

Juvenile Group. Sixty-two Cases			
		R-I	First Period.
		Per Cent	Per Cent
Good	16.1	38.8	40.3
Fair	32.2	32.3	46.8
Poor	51.7	28.9	12.9

A comparison of diabetic control in the group of juvenile diabetics is shown in Table 11. There have been six cases of coma and six of severe ketosis in six patients during the months of protamin insulin study. All have been treated with a combination of regular and protamin insulin. The usual routine has been to give both R-I and P-I at the beginning of treatment, and continue with frequent doses of R-I until there is clinical improvement and laboratory analyses indicate satisfactory control. Our impression has been that the duration of the acidosis is lessened and, more important, that the period of instability, which usually appears after adequate treatment with R-I, is less pronounced and of shorter duration.

ARTERIOSCLEROTIC GROUP

There are twenty-four patients of the arteriosclerotic group in the total cases studied. Eight

of these are insulin resistant and two are insulin sensitive. Seven patients have coronary sclerosis, and five of these have had definite attacks of angina. Four patients have had at least one cerebral hemorrhage. All of these patients except three have a severe degree of diabetes, and the three are of moderate severity. All have held a good control after the first period of adjustment except three, and these remain as difficult problems with P-I as they were on former R-I therapy. Three deaths have occurred in the entire group of 150 patients during the months of P-I study, and these all belonged in this arteriosclerotic group: one death from myocarditis, one from coronary thrombus, and one from advanced cerebral sclerosis. It is realized that no definite conclusion can be based on results of a study carried through for so short a time; but it is our impression that those patients of this group with anginal pain have had less frequent attacks, and that the pain has been less severe.

PROTAMIN INSULIN IN PRE- AND POSTOPERATIVE CARE

Experience with protamin insulin in pre- and postoperative care has been too limited for definite conclusions. With the few surgical patients for whom protamin insulin has been used, the maintenance of diabetic control after prolonged anesthesia has been very satisfactory. Only three cases have been observed and these are moderately severe diabetics. One patient received a single dose of ZP-I at the time of a midnight feeding, with early morning surgery following. Two received a single dose six hours before operation. All were adults and held full diabetic control after surgery for twenty-four hours without additional insulin.

SUMMARY

It is realized that conclusions on the results of protamin insulin treatment must be based on observations of less than one year. Also, some considerable part of the improvement here recorded might have been obtained with regular insulin therapy if the same close observation were followed, with the better degree of coöperation that could have resulted.

In the entire group of 150 diabetic patients now reported, the attempt in these studies has been to substitute one or two daily doses of protamin insulin for any number of doses of regular insulin that had been taken before, without making any change in the diet values or in the arrangement of meals in any way, except the addition of a night feeding when this had not been taken previously.

The entire group of patients included in this study have been problem cases, and were selected for this study because of the difficulties in maintaining satisfactory diabetic control with regular insulin.

Even in the mild and moderately severe diabetic patients, protamin insulin can give satisfactory results only when the problems of technique are approached as individual problems for each patient. As great a difference in individual absorption rate will be found in the mild as in the most severe patient.

In deciding the unit dose of protamin insulin, it must be kept in mind that the insulin has a U-40 strength. To secure the full unit dose prescribed it is necessary that the bottle be gently shaken in order to have an even distribution of the sediment, which contains an important part of the insulin dose.

Early morning hypoglycemic reactions are often due to an overlapping insulin effect, insulin from the injection of the previous morning and from the evening being actively absorbed at the same time. At the beginning of protamin insulin treatment, reaction symptoms may appear at irregular times during the day and night. These may be due to conditions of adjustment to the slow and gradual absorption of insulin, and appear to be more disturbing in those patients who have used regular insulin for several years. Close observation of these patients during their period of adjustment is important.

The recognition of patients who are classed either as insulin sensitive or as insulin resistant is important. The insulin sensitive patient appears to become more completely adjusted to a slow absorption of insulin and more able to maintain a diabetic control on one daily dose. In the 150 diabetic patients, over 56 per cent of the insulin sensitive group have been able to continue on one daily dose of the protamin insulin, as compared with 29 per cent among the insulin resistant cases.

CARDIOSPASM*

By H. BRODIE STEPHENS, M.D.
San Francisco

DISCUSSION by F. P. O'Hara, M.D., San Diego; John Hunt Shephard, M.D., San Jose.

CARDIOSPASM is the term used to describe that clinical condition characterized by a difficulty in swallowing, caused by an obstruction at the lower end of the esophagus in the region of the diaphragm. Despite the severity of the obstruction observed during life, though dilatation and hypertrophy of the esophagus are still present at necropsy, no obstruction can be found distal to the dilatation. Whatever the cause of obstruction during life, it ceases to act after death.

SUGGESTED HYPOTHESES

Many hypotheses have been suggested to account for the obstruction. These can be con-

Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

TABLE 1.—On Ten Patients With *Cardiospasm**

Initials	Age	Sex	Symptoms and Duration	Treatment		Symptomatic	Results	
				Type	Number			X-ray Appearance
I. C.	29	F.	Vomiting after eating, eight years.	Plummer dilatation, July to December, 1931	Several	Weight: 53.8 kilograms, 1931 Weight: 74.5 kilograms, 1935 No complaints, 1935		Dilatation with angulation in 1935; only dilatation in 1931.
P. G.	39	M.	Thought to have a carcinoma; considerable weight loss, several months.	Plummer dilatations, September, 1934..... July, 1935.....	4 5	Weight: 66 kilograms, 1934 Weight: 84.6 kilograms, 1935 No complaints		Dilatation of esophagus and spasm still present; slightly less than before treatment.
L. F.	60	F.	Difficulty in swallowing food, three years. Peptic ulcer, 1927, cured medically.	Esophagoscopy and bougie dilatations, July, 1933.....	4	Weight stationary. Very few symptoms. Improved by esophagoscopy, inadequately treated. Esophagoscope entered stomach easily in January, 1936.		Progressive increase in size of esophageal dilatation.
N. G.	33	M.	Recurrent attacks of vomiting, three years.	Esophagoscopy and Plummer dilatations, September, 1933..... October, 1933.....	5 2	Weight stationary. Fifty per cent improved two years after treatment.		Marked dilatation of esophagus before treatment. Slight improvement after five dilatations. Good case for operation, but patient refused.
R. B.	40	M.	Burning pain under the sternum, and loading up of food in the esophagus, relieved by vomiting, two years.	Esophagoscopy and Plummer dilatations, July, 1935..... December, 1935..... January, 1936.....	5 2 1	Twelve pounds gain in six months. Eating everything after eighth dilatation. Result: good.		Moderate improvement; question of duration, however.
R. D.	27	M.	Vomiting after eating, two years. Thirty pounds loss of weight.	Esophagoscopy and Plummer dilatations, January, 1933..... February, 1933.....	2 1	Ten pounds gained in two years. Paroxysmal attacks of difficulty in swallowing. Result: good.		Esophagus dilated three times normal size two years after incomplete treatment. Symptoms paroxysmal. Treated in psychiatric clinic.
M. R.	28	F.	Difficulty in swallowing, eleven years. Tube-fed for two years.	Esophagoscopy and Plummer dilatations; local application 25 per cent silver to ulcer at cardio-esophageal junction March to August, 1932..... January to February, 1933.....	8 2	Forty pounds gained in two years. No difficulty in swallowing. Clinical result excellent.		One year after dilatations instituted, x-ray shows esophagus much less dilated. Slight spasm with slight delay.
A. P.	42	M.	Difficulty in swallowing solid foods, four years.	Esophagoscopy and Plummer dilatations, October 8, 1932, to March 18, 1933.....	26	Twenty pounds gain in three years. No symptoms except for delay when excited or angry. Clinical result excellent.		Very slight delay three years after treatment. No dilatation of proximal esophagus. Good x-ray result.
A. E.	47	M.	Vomiting after meals, six months. Loss of weight, 35 pounds.	Esophagoscopy. Dilatations	None	Sixteen pounds gain in three months. Marked improvement by one esophagoscopy.		Esophagus dilated twice normal size. No change after esophagoscopy.
H. W.	56	M.	Regurgitation of food recently eaten, four years.	Esophagoscopy and Plummer dilatations, October 27, 1935, to November 19, 1935.....	9	Six pounds gain in three months. Clinically much improved.		After nine dilatations, esophagus still markedly dilated.

* Summary of Table 1: Number of males, 7; number of females, 3; ages, 27 to 60 years. Duration of symptoms, several months to 11 years. Clinical results, all improved clinically. X-ray appearance: Two showed decrease in size of esophagus by x-ray; eight were the same or worse.

veniently considered according to whether they postulate changes in the esophagus itself or in adjacent structures. In the latter group are included those cases possibly caused by kinking of the esophagus because of a deformity of the esophageal groove on the posterior surface of the liver (Mosher¹); an incoördination of the normal movement of the diaphragm during deglutition, with perhaps an actual spasm of the diaphragm (Jackson²); obstruction resulting from the action of the phrenico-esophageal membrane (Fulde³).

Hypotheses based upon changes occurring primarily in the esophagus center chiefly upon incoördination of the nervous mechanism of the cardia. Hurst⁴ assumes that there is a paralysis of the mechanism of the vagal opening. In Walton's⁵ opinion there is no paralysis, but rather a spasm in the region of the cardia. The difference in their views is well illustrated in relation to the passage of bougies. Hurst declares that a bougie will always pass the sphincter readily, without resistance; Walton, that the bougie is firmly gripped by the sphincter in its passage. It has been my experience that either bougie or esophagoscope will always pass through into the stomach readily. If either of these views is correct, there must exist at the cardia a true intrinsic sphincter, the tonus of which may be modified by the action of the extrinsic nerves.

KNIGHT'S STUDIES

Knight,⁶ working upon cats because the esophageal structure corresponds most closely to that of the human being, demonstrated that the interdiaphragmatic and intra-abdominal portions of the esophagus function as a true intrinsic sphincter, which is relaxed by the vagus nerve and contracts on sympathetic stimulation. The sympathetic supply arises from the celiac plexus in fibers that follow the course of the left gastric artery and its esophageal branch to the lower end of the esophagus. Knight was able to show definitely that bilateral vagal section reproduced the roentgen, pathologic, and clinical picture of achalasia of the cardia. The sphincter failed to relax. (Ferguson⁷ obtained similar results in monkeys while studying the effects of vagotomy on the gastric function.) If, however, celiac sympathectomy with a consequent denervation of the sympathetic fibers was performed at the same time that the vagi were divided, no obstruction resulted at the cardia; the sphincter always relaxed to allow the meal to enter the stomach. Knight concluded that whether the obstruction was caused by failure of the vagus or by spasm, in either case the integrity of the sympathetic supply is necessary for the obstruction to occur, and therefore it could be relieved by sympathectomy.

CELIAC SYMPATHECTOMY

At the time of Knight's report (January, 1935), seven patients had been subjected to the operation of celiac sympathectomy for the cure of cardiospasm. It was then too early for a complete report of the follow-up studies.

Accurate follow-up studies of the cases of cardiospasm treated by various means of dilatation are infrequently found in the literature. Knight's chart of sixty-six collected cases is surprising because of the high number of failures resulting from treatment by the various forms of dilators.

Knight's findings are substantiated by our study of ten patients, so far as the x-ray studies after dilatation are concerned (Table 1). The most noteworthy observation in these patients studied in our clinic is the marked symptomatic improvement, accompanied by gain in weight immediately following the institution of dilatation, by the Plummer dilator. Before undergoing this treatment the patients were observed both by the fluoroscope and the esophagoscope.

All of our patients were so much improved symptomatically following one or several dilatations that none of them was sufficiently uncomfortable to desire operative treatment.

COMMENT

The negative findings at necropsy in patients suffering from cardiospasm, together with the experimental observations up to the present time, point to a neurogenic origin for this clinical entity. The presence of a true sphincter at the cardio-esophageal junction is necessary for this theory to be tenable. Knight believes that he has shown a true sphincter to be present in the cat.

The condition of cardiospasm, whether resulting from vagal failure or sympathetic overstimulation, theoretically should be relieved by sympathetic interruption.

It has been shown in our own patients that dilatation by the various methods will bring about symptomatic relief in a high percentage of cases, yet the delay in the esophagus is still present. The symptoms of cardiospasm characteristically recur following dilatation, and are usually relieved by further dilatation. There has been no adequate explanation for the symptomatic relief obtained by the use of dilators, without appreciable change in the x-ray appearance of the delay at the region of the cardio-esophageal junction.

CONCLUSION

The operation of interruption of the sympathetic fibers running to the lower end of the esophagus from the celiac plexus, as suggested by Knight, is recommended for consideration in those patients with cardiospasm not relieved by dilatation. All of the patients in our series were improved sufficiently by dilatation so that operative intervention was not required.

DISCUSSION

F. P. O'HARA, M. D. (505 Medical-Dental Building, San Diego).—Most investigators consider cardiospasm to be due to some change in the nervous control over the esophagus. Many men have been seeking for some more adequate method of treatment than the dilatation of the cardia by mechanical means. Forcible dilatation no doubt relieves symptoms in a great number of these cases, but it has been found that these symptoms return and the actual deformity, as shown by x-ray, is unchanged. The work of Knight seems a definite step forward, and although it has not been tried in this country it deserves thoughtful consideration. We have found it difficult, so far, to persuade patients suffering from this condition to be operated upon, but think that time will soon make a change. It is a rather simple operative procedure, and its etiologic basis seems sound. Certainly, in some of the cases which have gone on for ten to twenty years, in spite of other forms of treatment, this procedure should seem advisable.

I have been particularly interested, not so much in cardiospasm, but in the "esophagismus" at other levels in the esophagus where we find spasm that will yield to simple repeated dilatation. In practically all of these cases it has been observed that there is a coexisting, rather localized arthritic spurring of the spine at the same level. Whether this condition may be stimulating the sympathetic innervation of the esophagus producing the spasm is merely conjecture, but I should be curious to know if other men have observed this same condition in cardiospasm.

JOHN HUNT SHEPARD, M. D. (608 Medico-Dental Building, San Jose).—The apparent infrequency with which a diagnosis of cardiospasm is made is, I believe, due to the fact that this clinical entity is not kept in the foreground of our minds. Some dysphasia is always present, and whenever a patient complains of dysphasia, substernal distress or discomfort in swallowing, or the eructation or vomiting of food free from any evidence of gastric digestion, an x-ray examination of the esophagus should be had, and if the roentgenologist is informed of the clinician's suspicion and uses a barium-acacia mixture in his examination, he will readily prove or disprove the presence of cardiospasm.

However, during the early stage, before dilatation of the esophagus has taken place, he may detect only a slight lagging of the barium column at the cardia, in which case subsequent examinations should be made. After dilatation or sacculization of the esophagus has taken place, the x-ray findings are most characteristic and only rarely can be misinterpreted. At times, dilatation of the esophagus may be so great that it will hold 1,000 cubic centimeters of material.

Symptomatic relief usually follows dilatation of the cardia, by the hydrostatic bag advocated by Plummer, the air bag as used by Smithies, or the large olive frequently used by Vinson. Doctor Stephens' experience in having to do multiple dilatations on the majority of his patients is not in conformity with the experience of several reported series. In the use of the hydrostatic or air bag, it is most advantageous to have one assuming a dumb-bell shape when completely distended, which prevents it from slipping out of the cardiac ring as it distends. The mid-portion of the dilating bag, when distended, should be an inch in diameter, and pressure of about 25 feet of water should be used. Unless dilatation is adequate, recurrences or incomplete relief is frequent. For the occasional case unrelieved by dilatation of the cardia, celiac sympathectomy should be done.

PANCREATIC SURGERY*

By GEORGE THOMASON, M.D.
Los Angeles

DISCUSSION by Walter A. Bayley, M.D., Los Angeles; H. Clare Shepardson, M.D., San Francisco; Charles E. Phillips, M.D., Los Angeles.

GREAT interest has been revived during recent months in the matter of certain phases of pancreatic surgery. I refer especially to the condition now termed hyperinsulinism, or hypoglycemia, and to malignancy of the pancreas. It is to the consideration of these two features that this paper will be confined.

In hyperinsulinism and hypoglycemia we believe that pancreatic surgery promises to take its place as an added triumph in the successful conquest of this recently recognized surgical entity. While comparatively few cases have thus far been reported, certain features involved are being clarified and give great hopes for the future of increasingly more successful methods and technique for combating this type of pancreatic pathology.

In the light of quite recent developments, it is certainly within the range of possibility that the hitherto apparently hopeless condition of carcinoma of the pancreas may yet be brought under somewhat more successful surgical control.

EARLY STUDIES

Considering, first, hyperinsulinism and hypoglycemia: In 1920 Joslin noted spontaneous hypoglycemia in certain diabetic patients. Two years later Fletcher and Campbell outlined in detail the clinical features of an overdose of insulin; and in 1924 Seale Harris recorded his observation of this same feature in certain types of asthenic patients preceding the noon meal. To Wilder should go the greatest credit for his valuable contributions in the clarifying of this subject, in that he and his coworkers established the pathologic proof of the association between spontaneous hypoglycemia and hyperinsulinism.

WHEN SUGAR EQUILIBRIUM IS NOT MAINTAINED

Dysfunction of the pancreas with hypoinsulinism develops hyperglycemia. Dysfunction of the pancreas with hyperinsulinism develops hypoglycemia. In either case it is fundamentally a question of the maintenance of sugar equilibrium. In these cases it seems quite evident that the secretion of several glands is directly involved in the pathologic physiology. Insulin from the islands of Langerhans tends to diminish the amount of blood sugar. Secretions from the medulla of the adrenal glands, from the anterior lobe of the pituitary and from the thyroid gland, tend to increase it.

If the blood sugar falls below a critical point in consequence of a deficiency, splanchnic neurons of the sympathetic system are set in action, as indicated by increased adrenal secretion. Both the

Fig. 1b.—Line of resection of the pancreas.

nerve impulses and the increased secretion of adrenalin have the effect of liberating sugar from the liver into the circulation, thus tending to restore the disturbed equilibrium. Cannon and his colleagues regard this as the first line of defense against a falling blood-sugar concentration.

HYPERINSULINISM WITH HYPOGLYCEMIA

Symptoms.—Symptoms of hyperinsulinism with hypoglycemia vary from a mere sense of weakness to attacks of unconsciousness and convulsions. It is probable that the symptoms are coincident with the lowered blood sugar, as the symptoms disappear after taking of food, especially sweets. Certain patients have developed the feature of setting an alarm clock to awaken them in the night and avoiding attacks by taking nocturnal feedings. The blood sugar may be normal between attacks. Symptoms of hypoglycemia usually begin to appear when the blood sugar is lowered to 70 milligrams per 100 cubic centimeters of blood. As a rule the lower the concentration of sugar the more alarming the symptoms become. However, in some cases the blood sugar may get as low as 40 milligrams before symptoms appear.

The most commonly observed symptoms are: A feeling of malaise, lassitude, and inability to perform even a moderate amount of physical labor. There is often trembling and sweating. There is usually a sensation of hunger which may be extreme or even agonizing. There may be mental confusion similar to that of alcoholic intoxication, and frequently a crisis resembling epileptiform seizures leading to a diagnosis of epilepsy. At times the neurologic and psychiatric aspects are so prominent that these patients are often referred primarily to a neurologist or a psychiatrist. Abdominal pain is sometimes pronounced. It may simulate appendicitis, gall-bladder infection or gastric ulcer.

PRESENCE OR ABSENCE OF ADENOMATOUS TUMORS

It is in those cases in which an adenomatous tumor has been found in the pancreas that surgery has achieved the most brilliant results in hyperinsulinism and hypoglycemia. An increasing

number of these cases are being reported in the literature. In a personal communication recently received from Professor Allen Whipple of Columbia University, New York City, he states that he has just done his seventh case in which he removed an adenoma from the pancreas. Evarts Graham of St. Louis and his colleagues report several cases, as have the surgical staff at the Mayo Clinic.

It is in those cases of hyperinsulinism and hypoglycemia where at surgery no adenoma of the pancreas is found that increasing interest centers. In the Colver Lecture on hyperinsulinism at our Medical School in Los Angeles in November, 1932, Doctor Wilder made the following statement:

"There is every reason to believe that improved surgical procedure will make it possible to obtain better results in cases of this kind. The operation is difficult technically and the surgeon probably has not removed enough of the gland. The situation is analogous to that of the early history in hyperthyroidism. The results in this new field ought to be as good as those now obtained in hyperthyroidism, and I predict that they will be."

Since Wilder made this statement at least two patients have been operated—one an infant, reported by Evarts Graham, and one an adult, a typical case of hyperinsulinism and hypoglycemia, operated by myself at the Los Angeles General Hospital, which two would seem to give some corroboration to Doctor Wilder's optimistic statement.

In every reported case in which no tumor had been found at surgery and partial pancreatectomy done, each surgeon in reporting his case stated that the disappointing results were probably due to insufficient pancreatic tissue having been removed. It certainly seems reasonable to conclude that if the capacity of the insulin factory is reduced a lessened output of the secretion must necessarily follow.

Credit for the diagnosis of the patient which came to me is due to my colleagues, Doctors Haining and Gilbert. Prior to the operation Doctor Haining noted on the patient's chart "statistically,

Fig. 2.—Operation completed.

the lesion is more liable to be a pancreatic (islet) adenoma. Probably pancreatic adenoma or pancreatic hyperplasia."

REPORT OF CASE

CASE 1.—The operation was performed September 17, 1934. There were several features of the operative technique somewhat different from any previously adopted. An upper right rectus incision was made. The gastrocolic omentum was sectionally ligated to its extreme left border. Elevation of the stomach gave excellent exposure of the pancreas. (Fig. 1a.)

Adopting the suggestion of Emile Holman, with reference to minimizing bleeding by ligating the splenic artery, we proceeded to do this—ligating the artery along the upper border of the pancreas and applying the ligature close to the head of the pancreas. The pancreas was separated a bit from below upward, sufficient to expose the splenic vein which was also ligated. The spleen was then easily removed, and the tail and body of the pancreas readily and quite bloodlessly lifted from its bed and dissected free from the posterior abdominal wall. The pancreas was held up and severed close to its head with a Percy cautery, and the proximal stump seared thoroughly with the cautery at a dull-red heat. (Fig. 1b.) A few chronic catgut sutures were taken in the stump as an extra, but possibly unnecessary measure. The gastrocolic omentum was resutured, a Penrose drain placed near the pancreatic stump, emerging through the resutured gastrocolic omentum and brought out through a stab wound in the side. There was practically no subsequent drainage and the wound promptly healed solidly. No adenoma was found in the removed specimen. (Fig. 2.)

The patient made an uninterrupted recovery. Two days postoperative the blood sugar was 138 milligrams. Five days later the blood sugar was 111 milligrams. From then until the present on an ordinary diet, even low in starch and without extra sweets, the blood sugar has ranged well within normal limits—from 87 to 91 milligrams. I have seen the patient within a month, and there has not been at any time in the twenty months intervening since the operation any return of his hypoglycemic symptoms. Preoperatively, at times his blood sugar had been as low as 40 milligrams per 100 cubic centimeters of blood.

COMMENT

As we stated in a previous paper, while one or two cases do not ordinarily prove much it seems

quite probable that with simplified technique and lessened surgical risk, subsequent experience and results will prove the subtotal pancreatectomy will give quite as much hope for this unfortunate class of patients as has been brought to those having adenomatous tumors. Further experience will also probably bring the answer to the question, "Will hyperactivity of the remaining pancreatic cells lead to exhaustion, atrophy, and degeneration?"

MALIGNANCIES OF THE PANCREAS

And now a brief discussion of the problem of malignancies of the pancreas. Surgeons have quite naturally hesitated to radically attack malignancies of the pancreas by reason of complicated anatomic features which so greatly increase the hazard of surgical intervention of this area, and, too, by reason of the very unfavorable results thus far connected with any attempt at radical surgery for malignancies in this location.

OPERATIVE PROCEDURES

Billroth, in 1884, successfully surgically removed the entire pancreas. Desjardins, in 1897, developed a type of operation for removal of the head of the pancreas, which represented an advance in surgical technique. The late Doctor Coffey of Portland did considerable experimental work in endeavoring to perfect a better technique in surgery of the head of the pancreas. Success in operations upon the body and tail of the pancreas have somewhat lessened the temerity in the matter of surgery of the pancreas.

The one particular feature which perhaps more than any other has contributed to failure of operations upon the head of the pancreas has been the apparent necessity for reintroducing into the gastro-intestinal tract the external pancreatic secretion, and which, of course, involved the connecting of the pancreas or its ducts with the bowel. As has been more recently developed by the wonderful work of Whipple and his colleagues, the preservation of the external secretion of the pancreas is apparently not imperative, and if more fully developed data proves this to be true it will remove one of the greatest obstacles to success in surgery dealing with malignancies of the head of the pancreas. In malignancies confined to the local area of the ampulla a number of successful operations have been reported, one recently a brilliant result by our colleague, Dr. Verne Hunt.

REVIEW OF THE LITERATURE

A review of the literature up to the present dealing with carcinoma in the region of the head of the pancreas shows something like eighty cases in which operation was done, and the immediate mortality was 35 per cent; 25 per cent surviving the operation and living for varying periods, but which were known to have had recurrences. It is more than likely that quite a percentage of the remaining thirty-four cases died from cancer, as the short follow-up gives no real clue to accurately determine this feature. There must have been a considerable number of unpublished cases in which the operation has been unsuccessfully attempted,

Fig. 3a

Fig. 3b

Fig. 3a.—First stage completed. Carcinoma of head of pancreas.

Fig. 3b.—Second stage completed. Head of pancreas and duodenum removed.

a recording of which would obviously make the statistical features still less favorable.

WHIPPLE OPERATION

Since it has been developed that possibly the external secretion of the pancreas is not absolutely indispensable, and with the observation that in many of these cases the pancreatic duct is already obliterated by the disease process, Whipple has developed a technique which seems to give promise of great additional value, and may possibly add, as Pfeiffer says, "a new and brilliant chapter to the surgery of this condition." The Whipple operation is of two stages:

1. A posterior gastro-enterostomy.

Ligation and section of the common duct, below the cystic duct, after determining the patency of the cystic duct, and leaving a long black silk ligature placed on the distal stem of the sectioned common duct to facilitate subsequent identification. (Fig. 3a.)

2. A cholecystgastrostomy.

Three to four weeks after the first stage the second procedure is carried out, consisting of:

(a) Ligation of the pancreaticoduodenal arteries, superior and inferior.

(b) Resection of the descending portion of the duodenum, with closure of the upper and lower ends, and a V-shaped excision of the head of the pancreas—wide of the growth, and including the ducts.

(c) Ligation of the cut end of the duct of Wirsung—and the duct of Santarini, if present—and suturing the two cut surfaces of the pancreas together tightly with silk. (Fig. 3b.)

WHIPPLE'S RESULTS

I quote from a personal letter received recently from Doctor Whipple: "I am very glad to report to you our results of the two-stage operation for removal of the duodenum, and part of the head of the pancreas, for carcinoma of the papilla. We have now carried out this operation in four cases, one having died of peritonitis, the result I think probably of the use of catgut instead of silk; a second lived for seven months and then returned with a severe biliary-tract infection and suppurative cholangitis which resulted in multiple ab-

scences and death. The autopsy showed liver abscesses and narrowing of the stump of his cholecystgastrostomy. The third case has now gone fourteen months. He also has had two more attacks of jaundice with a low-grade temperature, but has responded to cholagogues and shows no evidence at the present time of recurrence of his growth. The fourth case is one that I operated on only a month ago, so that it is too early to give much of a follow-up on him except to say that he stood the operation exceedingly well."

Doctor Whipple further states he has reports from one of the surgeons in Toronto telling him that he had performed the operation in two cases. The first one unfortunately died of pneumonia. This makes a total of six cases in which this technique has been used. The one patient living fourteen months with no external secretion escaping from his pancreas would seem a valuable contribution to the subject.

AUTHOR'S CASES

I performed this two-stage operation at the Los Angeles General Hospital on one patient, unsuccessfully, however, the man being seventy-four years of age and obviously a poor risk, but begging for relief. The second stage was done four weeks following the primary stage.

These two cases, the one in which all but the head of the pancreas was successfully resected for hyperinsulinism and hypoglycemia, and the one in which the head of the pancreas was resected, but unsuccessful so far as the life of the patient was concerned, while, of course, not giving from personal experience much data upon which to proceed, it does give considerable assurance that the mechanical difficulties of these operations are not insurmountable, and we have the courage to proceed further along these lines. Given younger patients, with early diagnosis of malignancy of the head of the pancreas, we believe this type of operation may give greater hope for better results than any previously devised.

SERIOUS FEATURES

There are, of course, formidable features which will perhaps always maintain serious hazards in this class of cases:

1. The surgeon is dealing with cancer.
2. The anatomic features involved are complicated.
3. The early symptoms are often obscure and simulate less serious conditions that lead to delay in diagnosis and the undertaking of remedial measures. Even the helpful diagnostic feature of jaundice is absent in 20 per cent of these cases.
4. The necessity of doing a cholecystgastrostomy with its potential ascending infection. Bernard has shown that at least 25 per cent of a large series of cholecystgastrostomies were followed by cholangitis. And Evarts Graham says: "The evidence with which I am familiar indicates that almost invariably the patient succumbs from multiple abscesses of the liver if the anastomosis remains patent." This is evidently what happened in one of Whipple's fatal cases.

5. Most of these patients, by reason of cholemia, liver damage, toxemia, a hemorrhagic diathesis, and asthenia are poor surgical risks, and with both stages of the operation very heavy surgical procedures, the operative mortality is certain to be high. But as against these we place the fact that these patients are well on the road to certain death, the itching of their icteric skin often intolerable, and their digestive disturbances most distressing, so much so that most of them will wish to risk the hazard of the operations. It is certain that the two-stage operation adds considerable to a more favorable prognosis, and the first stage will undoubtedly often bring much immediate relief to the patient.

IN CONCLUSION

As to the value, or lack of value, of this operation, time and experience alone will demonstrate. The combined experience of many surgeons will be necessary to properly evaluate it. And it is with the hope of stimulating renewed interest in pancreatic surgery for the conditions of hyperinsulinism and hypoglycemia, and in carcinoma of the pancreas, that this paper is presented to this Section today.

1217-1221 Hollingsworth Building.

DISCUSSION

WALTER A. BAYLEY, M. D. (1052 West Sixth Street, Los Angeles).—Doctor Thomason has given us an interesting report of his case of hyperinsulinism, or hypoglycemia, in which no adenoma of the pancreas was found. Evidently the removal of sufficient pancreatic tissue was all that was necessary to effect a cure. It has generally been thought that a tumor was present in such cases.

Although the operation becomes more formidable when a splenectomy is added, the great advantage of tying the splenic artery and vein early in the operation would seem to make this a necessity, at least in those cases where an adenoma or other tumor cannot be found and it is felt that much of the body of the pancreas must be removed.

In my first case I did not do this and, although I was able to remove over three-fourths of the body of the pancreas, the patient died of his disease fourteen months later; and autopsy disclosed a small adenoma in the posterior wall of the remaining stump of the pancreas. This tumor was only five centimeters from the duodenal border of the head of the pancreas.

In removing the head of the pancreas for carcinoma, the operator is faced with what is probably one of the most difficult operations in abdominal surgery. I doubt if many of these operations will be done, especially as most of the patients are elderly and generally in poor condition when they come to surgery. The condition has generally progressed so far that, when operation is done, about all that is feasible is an anastomosis between the gall-bladder and duodenum or stomach. This is of great advantage to the patient, and will make his remaining days much more comfortable.

However, the technique so well described by Doctor Thomason should be kept in mind, as there is always the possibility of an early case being found during the course of an exploration of the upper abdomen. The patient would then be given an opportunity for recovery from an otherwise fatal condition.

✱

H. CLARE SHEPARDSON, M. D. (384 Post Street, San Francisco).—Gradually the several syndromes produced by under- and overactivity of the various ductless glands is becoming recognizable. Yet the confusion which still exists concerning the morbid factors responsible for certain more or less isolated symptoms must be clarified before we can hope to apply adequate therapeutic measures. As a result, from the internist's point of view, a word of caution should be interpolated to properly appreciate this excellent paper.

No doubt the surgical technique so concisely described by Doctor Thomason is excellent, and comments concerning this portion of his discussion, for obvious reasons, should be confined to those listeners who are surgeons; yet it should be emphasized that adequate anatomical diagnosis is absolutely essential before the surgical procedure described can be undertaken. Hyperinsulinism and hypoglycemia are not synonymous terms; for while excessive activity of the pancreas resulting from either hyperplasia of the islet cells or actual tumor formation brings about a marked depression in the blood sugar, with a consequent chain of symptoms, many instances of glycopenia may result from causes entirely unrelated to alterations in the hormonopoeitic activity of the pancreas. Glucose is one of the principal sources of cellular nutrition, and elaborate hormonal and nervous regulation is provided to maintain a fairly stable concentration of this substance in the blood. Not only are several of the glands of internal secretion engaged in this regulation but, in addition, a nervous control is maintained either directly through the liver or indirectly by way of the pancreas and suprarenal glands.

The chief source of the blood sugar is the store of glycogen in the liver. Consequently any interference, either organic or functional, with the production of glycogen, the storage of glycogen or gluconeogenesis occurring in the liver, can result in the production of hypoglycemia.

Furthermore, the work of Houssay, Evans, and others, seem to indicate that only in the presence of a properly functioning adenohypophysis can normal carbohydrate metabolism proceed. As a result, certain of the functional disturbances of the anterior pituitary body are associated with glycopenia, which may be sufficiently severe to produce definite symptoms.

And it has been established, furthermore, that variations from functional normality of at least one other ductless gland, namely, the adrenal cortex and possibly, also, the medullary portion of the suprarenal bodies, sometimes are associated with profound disturbances in carbohydrate metabolism.

Finally, hypoglycemia has been demonstrated in starvation, severe and strenuous exercise, progressive muscular atrophy and in status thymicolymphaticus. In these extrainsular disturbances, where pancreatic surgery, obviously, is not indicated, dietary measures may be resorted to, often with gratifying success. Usually frequent carbohydrate feedings are suggested, but occasionally such extra consumption of glucose may actually stimulate the Langerhans islands to an even greater production of insulin, and thus defeat the object to be attained. High-fat diets avoid this complication and raise the blood sugar. Unfortunately, prolonged use of a high-fat menu is difficult in ordinary ambulatory life.

The clinical acumen of Dr. Seale Harris, in recognizing the possibility of pathologic lesions of the pancreas as being the etiologic factors responsible for the syndrome he described, has been adequately acknowledged by many investigators. And it is obvious that surgical intervention, with removal of an adequate portion of the pancreas, in those cases whose symptoms result from spontaneous hyperinsulinism, offers the chief means of therapeutically attacking this problem. It is necessary, therefore, for the surgeon to develop the technique of pancreatic surgery in the same manner that, for example, the technique of thyroid surgery has been developed. The difficulties inherent in pioneer surgery must be studied and overcome in exactly the manner undertaken by Doctor Thomason, together with such men as Whipple of New York and Holman of San Francisco, before the many disappointments can be eliminated and favorable results anticipated. Doctor Thomason should be congratulated for the timeliness of his researches, and his thesis highly commended.

✱

CHARLES E. PHILLIPS, M. D. (2007 Wilshire Boulevard, Los Angeles).—The author is to be highly commended for this contribution to the subject of pancreatic surgery. It is a field which has advanced with our knowledge of the physiology and pathology of the organ.

The surgical correction of hyperfunction, together with the removal of cysts and new growths affecting the pancreas, has become a reality. Only twenty-five years ago

I reported the first successful removal of a hydatid from the pancreas.

At the present time, we attack the nonmalignant tumors of the pancreas with confidence. The acute infections are diagnosed without a wide margin of error, and surgical interference seems to have resulted in a distinct improvement in results.

The clinical diagnosis of the neoplasms of the pancreas leaves much to be desired. Localized infections and inflammatory cysts may so closely simulate malignancies that radical removal of pancreatic tissue at a time where a cure for malignant tumors is possible may lead us to radical removal of relatively harmless structure, with unnecessary danger to the patient.

Four personal cases, all apparently alike, will illustrate a tumor-like mass found in the head of the pancreas presented all of the clinical aspects of malignancy, with common-duct occlusion at the ampulla. Palliative surgery was performed in all of the cases, consisting of a cholecystoduodenostomy. There were three complete recoveries, proving that the condition was benign in three of four cases. The fourth case went on to rapid termination.

Where the diagnosis is certain, radical surgical attack is justified and gives hopes for otherwise terminal condition in malignancy of the pancreas. The essayist has shown that surgical interference in cases of hyperinsulinism is clearly indicated. The pancreas offers a relatively new and most interesting field for surgical endeavor.

SURGICAL TREATMENT OF STOMACH ULCER*

By CHARLES EATON PHILLIPS, M.D.
Los Angeles

DISCUSSION by Verne C. Hunt, M.D., Los Angeles;
Asa Weston Collins, M.D., San Francisco; George
Thomason, M.D., Los Angeles.

EFFORTS directed toward the relief or cure of any disease condition should be guided by a comprehensive idea of its cause, development, possible sequelae and the factors leading to its recovery. This is particularly true concerning the relief and cure of stomach ulcers.

The question of surgical intervention depends on the prognosis following medical management on one hand, and the expected benefits and dangers of attending operative interference on the other.

PATHOGENESIS

We know no specific cause for stomach ulcers. Like those developing in other parts of the body, there are probably a number of activating factors causing the condition. In order of their importance we may enumerate:

First: Undiluted gastric juice. This will almost certainly cause ulcers, as has been shown by the experiments of Mann,¹ Dragstedt,² Ochsner,³ and others. Undiluted gastric juice may result from functional, mechanical or mental disturbances interfering with the normal working of the stomach.

Second: Infections. About 50 per cent of stomach ulcers show the presence of infectious organisms. The presence of contact ulcers in a lesser number show the relative importance of infection as an etiologic factor.

Third: General physical impairment with lack of tissue resistance predispose to their formation.

Fourth: Mechanical irritation is a minor factor responsible for some.

Fifth: Heredity and external trauma are occasional factors.

Of these causes, the presence of undiluted gastric juice is the most important. Experiments have shown that not only does undiluted gastric juice cause ulcers, but the neutralization of the acid results in their prompt relief. Of equal importance, it has been shown that the normal sequence of the gastro-intestinal tract is essential to health and function. For example, the elimination of the neutralizing action of the duodenum (by sidetracking operation) will result in frequent ulceration when the stomach contents are passed directly into the jejunum. When the stomach contents are diverted into the ileum, ulcerations almost surely follow.

DIAGNOSIS

A fairly characteristic symptomology consisting of food pain, hematemesis, melena, abdominal pain, localized tenderness, nausea and vomiting, and finally the visualization by the x-ray, in suitable cases, establishes the diagnosis of ulcer.

TREATMENT

The treatment of stomach ulcers is a medical problem except in fairly well defined limits. In early adult life the treatment is medical until such time as there is a reasonable doubt that a cure can be effected; in other words, after there have been relapses following apparent cures, and this has been repeated with the patient exercising reasonable care in diet and habits of living. It is better to consider the case surgical rather than to risk perforation, hemorrhage or long invalidism and ultimate malignancy, by further medical treatment. In later life, lowered resistance and the increased risk of malignancy shorten the legitimate time for medical treatment. Any treatment other than that necessary for operative preparation may be contraindicated.

The size, location and physical characteristics of the ulcer, together with the age and general physical condition of the patient, determine the time and character of the operation. The size of the ulcer has little significance regarding its probable malignancy. Many large ones are benign and many small ones are malignant.

Indications for Surgical Relief.—Indications for surgical relief depend on (a) the patient, his age, family history of ulcer and cancer, his adaptability to follow a medical cure; the urgency and duration of the symptoms; and the size and location of the ulcer. (b) The doctor. Indications for operation vary with the ability of the operator. One surgeon may resect a stomach ulcer with ninety-eight chances in a hundred that the patient will recover, while another operator may be able to offer the patient only fifty to seventy-five chances of recovery in the same series. The patient would be a good risk in the hands of one, while the operation would be contraindicated in the hands of another.

Surgery for relief of gastric ulcer has undergone great changes in the past decade. The opera-

* Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

tion of gastro-enterostomy has been followed too frequently by bleeding ulcers, cancerous degeneration in remaining ulcers, dumping stomachs and jejunal ulcers. The logical treatment of ulcer is that of resection of the ulcer-bearing area, and the restoration of the normal sequence of the gastro-intestinal tract. For obvious reasons, the preservation of the duodenum, with its essential buffer substances, is desirable. When extensive pathology requires that anastomosis be performed between the stomach and the jejunum, it is essential to remove a larger part of the secreting surface of the stomach to reduce the acid content of the gastric secretion.

The results following the radical removal of the distal half of the stomach more than justify the added difficulties of operation.

A comparative table of results of gastro-enterostomy and partial gastrectomy, by Richard Lewisohn,⁴ with a follow-up over a five-year period, show that about eighteen times as many jejunal ulcers follow gastro-enterostomies as occurred in the same number of resections. These were the results found by a subsequent operation. Ulcers of the stomach requiring surgery for their relief are entitled to resection when the patient's condition will permit. By resection we include the distal half of the stomach, where over 80 per cent of the ulcers are found. The removal of this portion of the stomach not only removes the majority of the ulcer-bearing area, but also such a part of the acid-secreting surface that further ulceration is rare.

Pyloroplasty furnishes a logical restoration of the gastro-intestinal tract, permitting the normal neutralizing of the gastric juice by the mixture of the duodenal secretions and at the same time preservation of the normal sequence of the gastro-intestinal tract.

Fig. 1.—Contour of normal stomach, showing extent of gastric resection.

Fig. 2.—Extent of gastric resections with accommodating incisions.

Its disadvantages consist in difficulties of operative technique, but chiefly it does not remove the parts most liable to suffer subsequent pathologic changes. The development of ulcer surgery has been toward the wider removal of the ulcer-bearing area, and the attaching of the open end of the stomach to the side of the duodenum. The author's technique has been similar to that described by Horsley⁵ for the relief of cancer of the stomach.

PROCEDURE IN OPERATION

After preliminary preparation, a Levine tube is passed into the stomach through the nose before the anesthetic is started. Adequate exposure is afforded by a paramedian incision extending from the ensiform to the right of the umbilicus. The lesser peritoneum is explored by the finger through the gastrohepatic omentum. The extent of the pathology and the mobility of the stomach are determined. The gastrocolic omentum is opened, and Pahr clamps are applied across the stomach, which is severed between them by the cautery. The distal part of the stomach is turned to the right and the pylorus is freed to the first portion of the duodenum. A small Pahr clamp is placed just beyond the pylorus. The pyloric artery is tied. A crushing clamp is not applied to the duodenum, but the blood supply is controlled by the left thumb and finger until the bleeding points are picked up individually and tied. A clamp devitalizes the tissue to be approximated and may result in an insecure hemostasis.

The second portion of the duodenum is mobilized by incising the reflection of the peritoneum to the right. The duodenum is then rolled over on its mesentery, so that it approximates the stump of the stomach which is mobilized by incising the gastrocolic omentum. The anterior side of the duodenum is split down its long axis for about two inches, so that the open end and side of the duodenum will approximate the cut end of the stomach. The posterior side of the cut end of the stomach is fixed to the superior border of the duodenum, while the greater curvature of the stomach is fixed to the bottom of the incision made in the second portion of the duodenum. The serous and muscular coats of the stomach are attached to the corresponding layers of the duodenum by a continuous suture of chromic gut. The mucosa is then approximated by a running stitch of the gastro-intestinal suture, accurately approximating the mucosa of the stomach to that of the duodenum. The Levine tube, which was passed into the stomach before the anesthetic was started, is now adjusted in the stomach or passed into the duodenum if desired. The anterior row of sutures completes the anastomosis. This is further reinforced by another row of mattress sutures of silk or linen. The closure of the abdominal wall should be secure and adequate, as tissue repair may be slow in those suffering from malnutrition. Preference is for a forty-day chromic stitch for closure of the fascia.

With very extensive pathology the operation of a subtotal gastrectomy may be indicated. The so-called Polya method of closure may be the method of choice in effecting the restoration. The duodenum is closed by infolding and suturing to the pancreas. The anastomosis is completed by an end-to-side closure, the stomach to the jejunum. Theoretically as well as practically, it is desirable to resect much of the acid-secreting surface of the stomach before the anastomosis is completed with the jejunum. It is only by this mechanical lowering of the acidity of the stomach that the jejunum is able to stand the direct action of the gastric juice.

COMPLICATIONS

Hemorrhage.—Hemorrhage occurs in 8 per cent of stomach ulcers, and is responsible for a mortality of 16 to 29 per cent of those affected (Finney⁶). Hemorrhage becomes a surgical problem when a known localized ulcer continues to bleed after adequate medical treatment has been administered. It becomes a surgical problem while the patient is still able to stand operation. Competent operative interference will reduce the mortality rate from one-half to one-fourth of the prevailing rate, attending the so-called conservative treatment. Surgical intervention should consist of attack on the bleeding point. Excision of the ulcer, hemostasis and careful closure of the mucosa in the least possible time consistent with good work is essential. Hemorrhage from an unlocalized lesion is not surgical.

Perforation.—Perforation occurs in over 25 per cent of ulcers, and accounts for 7 per cent of the deaths (Finney⁶). The treatment of perforation is immediate operation. The mortality in-

Fig. 3.—Gastro-duodenal anastomosis completed.

creases with each hour of delay. Perforated ulcer treated surgically within the twelve hours shows a mortality of about 10 per cent. When the operation is delayed the second twelve hours, the mortality becomes double or more. After twenty-four hours' time has elapsed nine out of each ten have lost their chance of recovery. The administration of opiates before a positive diagnosis has been made is usually responsible for the delay in operation.

Where there is a history of preëxisting ulcer, and the patient is seized with sudden pain, shock, abdominal rigidity along with typical blood changes, the diagnosis is easy. In atypical cases, without ulcer history and with comparatively mild symptoms, the condition may be overlooked. The administration of morphin before diagnosis is made becomes the patient's death warrant. X-ray evidence of air in the subphrenic space becomes a positive symptom when found, but its absence should not even delay operation when the other symptoms of perforation are positive. Operation consists of closure of the perforation and drainage. Excision of the ulcer may facilitate closure; a longitudinal incision and a transverse closure when the perforation is near the pylorus relieves obstruction. Closure of the perforation should be followed by a removal of the extruded stomach contents. Drainage should be inserted to the bottom of the pelvis and brought out through a suprapubic stab wound. Accumulations to the outer side of the cecum should be removed and drained by a separate stab wound made to the mesial side of the iliac spine when necessary.

Ulcus Carcinomatosus.—Signs of malignant changes call for a wide resection of the ulcer together with a removal of all tributary glands. Attachments to the pancreas are removed by the cautery, and drainage is inserted to the damaged pancreatic tissue. Restoration of the gastro-intestinal tract depends on the amount of tissue

removed. The end of the stomach to the side of the duodenum is the method of choice. Where these structures cannot be approximated, the restoration may be effected by the so-called Polya or by a Bilroth II. With multiple ulcers near the cardia, a complete gastrectomy is indicated where there is a fair chance of success. Gastro-enterostomy is used only as a palliative operation.

Many apparently hopeless cases have passed the two-, three- and five-year periods without recurrences. The patient should be given an opportunity to recover by radical surgery even though the chances seem to be small.

IN CONCLUSION

Removal of persistent pathology and restoration of the normal sequence of the gastro-intestinal tract is the aim of surgery. Surgical relief of ulcer should not be undertaken by the casual operator. The mortality rate follows too closely the ability of the surgeon to permit of uncertainty. The average surgeon will not attempt the removal of a cataract, yet failure would result only in the loss of an eye. Lack of skill or of judgment in stomach surgery results in the patient's death. The field of stomach surgery has great possibilities. Regard for the lives of patients and for the reputation of the profession demand care and efficiency in this work.

DISCUSSION

VERNE C. HUNT, M. D. (727 West Seventh Street, Los Angeles).—It is well known that malignant degeneration of a duodenal ulcer practically never occurs, and that primary malignancy at the site of a previously existing duodenal ulcer seldom, if ever, occurs; and, furthermore, that excision of a duodenal ulcer is not necessary in the course of a surgical procedure to produce a satisfactory result, in terms of permanent relief of all symptoms. Because a small percentage of chronic gastric ulcers undergo malignant degeneration, and because in a larger percentage of cases it is difficult and often impossible clinically to differentiate a benign gastric ulcer from an early primary carcinoma, or from a carcinomatous ulcer of the stomach, it is essential, in the surgical treatment of a gastric lesion, to excise the lesion as part of the surgical procedure. Little difference of opinion exists regarding this principle. Excision of most gastric ulcers may be accomplished by either relatively conservative methods or by radical partial gastrectomy. Not all gastric ulcers are amenable to surgical excision. In a recent review of 131 cases of gastric ulcer that I have operated upon, it was found that in 14 per cent of the cases the lesion was situ-

ated in the relatively inaccessible cardiac third of the stomach, either on the posterior wall or at the lesser curvature; in which instances excision was not readily instituted. There were others in which their high situation, or where protective perforation of a large ulcer posteriorly made excision inadvisable. In 20 per cent of the cases of gastric ulcer, excision of the lesion, for one reason or another, was not carried out, but instead the indirect operation of posterior gastro-enterostomy was employed. In the remainder of the cases the relatively conservative surgical procedure of local excision of the ulcer and posterior gastro-enterostomy was employed in 71 per cent of the cases, and partial gastrectomy in 29 per cent of the cases. The selection of the surgical procedure best suited to the individual case is based largely on the size and location of the lesion. Experience has adequately proved that the operation of local excision of a small benign gastric ulcer in the pyloric or middle third of the stomach and posterior gastro-enterostomy has been productive of excellent results, with few recurrences of a gastric ulcer and few instances of recurrent ulcer at or about the gastro-enterostomy stoma. In the cases of large gastric ulcer in an accessible portion of the stomach, and particularly such lesions in which, upon inspection and palpation, it is impossible to dismiss the question of a malignant lesion and in which gastric resection may be carried out, partial gastrectomy is the operation of choice. The method of establishing gastro-intestinal continuity following partial gastrectomy, whether by the Billroth No. 1 procedure, the gastrojejunal end-to-side method of Polya, or the gastroduodenal end-to-side anastomosis as described by Doctor Phillips, is dependent upon many factors, and the surgeon will usually select the method best suited in his hands to the situation as he finds it. There is much on a physiologic basis to urge the utilization of end-to-side gastroduodenal anastomosis, as described by Doctor Phillips as the method of choice in restoring gastro-intestinal continuity after partial gastrectomy when it may be accomplished readily. It is noteworthy, however, that sufficient mobilization of the duodenum is not always readily accomplished to facilitate such an anastomosis with maximum assurance of satisfactory post-operative function. Doctor Phillips has brought to your attention a method of establishing gastro-intestinal continuity after partial gastrectomy, which is applicable in certain cases, and physiologically fulfills certain prerequisites to the elimination of new anastomotic ulcers, which are not fulfilled entirely by the usual methods of reestablishing gastro-intestinal continuity.

I should like to ask the question, "What has been the mortality rate of this particular procedure in the surgical treatment of gastric ulcer?" While the operation of partial gastrectomy is the operation of choice or necessity in certain gastric ulcers, the relatively low mortality rate and the excellent results of the conservative surgical procedure of local excision of a gastric ulcer and posterior gastro-enterostomy should not be forgotten.

✽

ASA WESTON COLLINS, M. D. (450 Sutter Street, San Francisco).—My experience in partial removal of the stomach and gastro-enterostomy consists of over 200 cases, practically all directed toward the relief of pyloric and duodenal ulcer.

In an article published in *CALIFORNIA AND WESTERN MEDICINE* in September, 1931, I reported ninety-four cases, with a mortality of 5.25 per cent. All of these cases were operated by a method of my own, which is a modification of the Doyen operation. There are four points to be observed in all operations: No leakage, no hemorrhage, rapid technique, and no tension of any of the structures. There are two chief functions of the gastro-intestinal tract: First, digestion and second, motility. If anything interferes with the free movement of peristalsis, trouble starts.

Faulty technique is the cause of failure in practically all operations in this field. If the technique is perfect, all should survive. Shock is overcome by rapidity of operating, and the manual dexterity of the operator insures against hemorrhage and leakage. Plastic work on the stomach or intestine is meticulous, and I quite agree with Doctor Phillips that this type of surgery should be con-

fined to a few well-qualified surgeons. I do not believe that there is any one standardized operation to be used in all cases. Silk and linen are nice to work with, but I never use them.

The point that Doctor Phillips wants to put over, as I take it, is the removal of as much of the pyloric end of the stomach as possible, to prevent postoperative jejunal ulcer from the acid of the stomach. This he has done very nicely, and I quite agree with him.

GEORGE THOMASON, M. D. (606 South Hill Street, Los Angeles).—Perusal of Doctor Phillips' paper discloses much for approval and very little ground for difference of opinion.

Certain features of the paper will bear repetition, merely by way of emphasis; as, for instance, that the treatment of stomach ulcer in early life is certainly medical, as such a large majority of them have so strong a tendency to spontaneous healing if given a fair opportunity by means of a carefully regulated regimen, intelligently and faithfully carried out by the patient.

In harmony with the sentiments of the paper we cannot justify the all too radical procedure of extensive gastric resection for ulcer in younger patients, as so generally practiced by Continental surgeons, and by a few in this country as a routine practice. The simple procedure of excision of the ulcer and a pyloroplasty will be feasible in a majority of these cases, and the pyloroplasty will sufficiently modify the gastric function and secretion as to make any recurrence of the ulcer but a remote possibility.

Boldyreff of Battle Creek, Michigan, was evidently correct in his contention that the level of gastric acidity under normal circumstances is regulated by the neutralizing effect of the pancreatic juice, which gains access to the stomach by reflux through the pylorus. This feature was later confirmed by the researches of Olch and Elman. A pyloroplasty, by removing sphincteric action of the pylorus, certainly greatly facilitates this reflux of alkaline juices, thus lowering gastric acidity.

While most of the resections of the stomach do not actually remove the acid-producing glands—these being largely located in the cardia—the resection does take away the area in which the reflex stimulation of the peptic glands originates, and produces, according to Lewisohn, at least a hypochlorhydria in more than 80 per cent of cases. In cases in which conditions are present, so as to make pyloroplasty impractical, certainly resection should be done in preference to an excision of the ulcer and gastro-enterostomy. In older patients, because of the increased danger of malignancy complicating the ulcer, and in younger individuals where less heroic measures cannot safely be utilized, resection is obviously the procedure of choice.

Doctor Phillips states: "The indications for operation vary with the ability of the operator." While this unfortunately is true, it is to be deplored, and the ideal procedure could be carried out if only experienced and wholly qualified surgeons would undertake this testing type of surgery.

The type of operation which Doctor Phillips outlines, the modified Billroth No. 1, by preserving the continuity of the normal gastro-intestinal tract in reestablishing the connection between the stomach and duodenum, is undoubtedly the most desirable when possible to perform. It is surprising at times the amount of stomach which can be removed and still have the cut edge of the stomach brought over to the duodenum. When this is done, we believe it is desirable to tack the stomach to the round ligament of the liver with a few interrupted sutures, which will greatly relieve the tension upon the suture line.

DOCTOR PHILLIPS (Closing).—Doctor Hunt has included duodenal ulcer in the scope of this discussion of the treatment of stomach ulcer. I believe it really belongs there. Granted, duodenal ulcer rarely, if ever, becomes malignant; yet the fact that it frequently does not heal, bleeds and sometimes perforates, following surgery which does not remove it, is sufficient reason for its removal when it can be performed without undue risk to the patient.

In operating on gastrojejunal ulcers, I have found the duodenal ulcers still active in several cases. The longest period of activity of a duodenal ulcer, following a gastro-enterostomy, noted in my work, was one of over fifteen years with serious exsanguination occurring several times during that period. These findings have convinced me of the necessity of removing ulcers of the duodenum, consistent with the safety of the patient. We have also encountered perforations of duodenal ulcers following functioning gastro-enterostomies.

Doctor Hunt has pointed out the impossibility, in all cases, of clinically determining the malignancy of stomach ulceration. Safety demands the wide excision of all ulcers and the adjacent glands such as can only be accomplished by gastric resection.

The operation I have described permits the wide removal, with comparative ease, of the distal half of the stomach, the adjacent glands, and first portion of the duodenum. Ulcers of the fundus of the stomach show such a high percentage of malignancy as to require their radical removal routinely.

I have found that about 80 per cent of the cases of stomach ulcers can be readily removed by the resection and duodenal anastomosis described. The remainder should be resected, and the continuity of the gastro-intestinal tract be restored by the methods of Polya or Billroth, or by total gastrectomy. Local excision is not sufficient where malignancy may exist.

There has been no mortality in uncomplicated cases since I have adopted this method. There has been no untoward results in these few cases (twenty). Convalescence has been shorter, and the gain in weight and strength has been much more rapid than in any other type of stomach operation. The results have been much superior to others in a previous series of two hundred cases of stomach ulcer treated by gastro-enterostomy and pyloroplasty.

The mobilization of the duodenum need not be carried on to any great extent. In cases of ulcer of the first portion of the duodenum, a moderate displacement of the duodenum is met with a wide displacement of the stomach to the right.

In the removal of gastrojejunal ulcers, following gastro-enterostomy, where the enterostomy was placed well to the left, it was necessary to resect not only the enterostomy opening but also the duodenal ulcers, which were still active. The results were a fundus lying in the midline, and the line of anastomosis was to the right. The results in these cases were the same: the patients noticed hunger a little sooner, and the added food caused a little more rapid gain in weight. Comparing the results of gastro-enterostomy, pyloroplasty and resection, I am convinced that in suitable cases resection offers the greatest chance for complete recovery.

The dangers of resection in competent hands are not larger than in gastro-enterostomy or pyloroplasty. Doctor Collins made a statement which I wish to emphasize: "Faulty technique is the cause of failure in practically all operations in this field." I would substitute "mortality" for "failure." The aim of the operation is not only to prevent jejunal ulceration from lowering the acidity of the stomach, but, more important, it furnishes an opportunity to remove a large majority of the ulcers and ulcer-bearing area in the stomach, and at the same time reestablish the continuity of the gastro-intestinal tract so that subsequent ulceration will be almost unknown.

Doctor Thomason has brought up the question of reduction of the acidity of the stomach following the removal of the pyloric sphincter by the influx of the duodenal secretions into the stomach.

Dr. Emmet Rixford brought out the theory of gastric secretion, that our progenitors gulped large chunks of food, which were unable to pass the pylorus. Nature remedied this by an outpouring of additional gastric secretion digesting the pieces so they could pass the pyloric sphincter. This inheritance possibly explains the hypersecretions in duodenal contraction. Hyperacidity depends on the reflex set up by the presence of food trying to pass the pylorus. Section of the pyloric end of the stomach destroys the reflex arc responsible for the excess acid secretion. The radical reduction of acidity removes the chief cause of

ulceration, and removing the part of the stomach most liable to ulceration reduces the incidence of ulcer to a minimum.

In conclusion, I wish to emphasize that the field of stomach surgery should be restricted to those adept and thoroughly trained. The average doctor may not attempt many operations where there is little danger to the patient's life, but he will sometimes attempt to remove stomach ulcers when lack of efficiency means death to the patient. Lack of skill is responsible for 90 per cent of the accidents of gastric surgery.

I deeply appreciate the discussion of Doctors Hunt, Collins, Rixford, and Thomason; they have added much to this brief presentation.

OSTEOMYELITIS AND SUPPURATIVE JOINTS: SALT WATER POOL TREATMENT*

By A. BROCKWAY, M.D.
Los Angeles

DISCUSSION by Francis M. McKeever, M.D., Los Angeles; Frederic C. Bost, M.D., San Francisco; Samuel S. Mathews, M.D., Los Angeles.

THESE two conditions, osteomyelitis and suppurative arthritis, are presented together as one subject because they are closely allied clinically, and are also often associated together as part of the same infection process. However, from the standpoint of treatment, they should be considered as separate clinical entities because, as will be shown later, the fundamental principles underlying their treatment are distinctly different.

Most of the various antiseptic formulae that have been developed have been tried in the treatment of osteomyelitis, but the ideal antiseptic that will destroy bacteria in the living body without harming the tissues has not been found. In osteomyelitis, particularly, such form of treatment is futile, because the solution cannot possibly reach the microscopic limits of the infection.

With the advent of bacteriophage treatment, the medical profession had high hopes that here at last was a form of therapy that would have a direct and beneficial therapeutic effect in osteomyelitis. From a theoretical standpoint this would seem the ideal way to deal with any type of infection; but, in spite of all the theoretical implications, the fact remains that the stubborn course of bone infection has not been greatly altered.

I think the same may be said of maggot therapy. There is no doubt that good results have been obtained with this mode of treatment, and the same may be said of other forms of treatment in use. Many cases of osteomyelitis, either because of the low virulence of the organism or the high resistance of the host, tend to be a self-limiting disease and eventually get well. However, acute bone infections remain one of the most intractable conditions that the surgeon is called upon to treat.

The fundamental principles underlying the treatment of infection have been known and practiced for a long time. These two cardinal principles—adequate drainage and rest—are as true and impor-

*From the clinics of the Orthopedic Hospital, Los Angeles.

tant today as they were in the earliest days of surgery.

The practical application of these principles in the treatment of osteomyelitis is best exemplified in the Winnett Orr treatment. When meticulously carried out, this method not only satisfies the two prime tenets of adequate drainage and rest, both local to the diseased part and general rest of the patient, but it also prevents contamination from frequent dressings. I think it may be said without much fear of contradiction that the Orr treatment has given on the whole to surgeons over the country a degree of success that has not been approached by any other form of treatment.

In spite of the above statement, I believe that this treatment has definite shortcomings in certain types of cases. When the infective process is in close proximity to the major joints, especially when located at the distal end of the femur or near the elbow joint, and more particularly if there is an accompanying suppurative arthritis of the neighboring joint, then one of our main problems in treating this patient is to preserve for him as much joint motion as possible. Restoration of motion in a pus-ridden joint is not best accomplished by a long period of immobilization in plaster casts.

It is in support of this contention that the salt water pool treatment of bone and joint infections is here described. While we have used this treatment in over a hundred cases of osteomyelitis, this paper is concerned only with suppurative arthritis and osteomyelitis in which adjacent joints are also involved, or when the diseased process closely encroaches upon joint structures. It is in these particular types of cases, in which preservation of joint motion is one of the vital issues, that the salt-pool treatment has its greatest field of usefulness.

ACUTE SUPPURATIVE ARTHRITIS

It was first shown by Willems during the World War, and it has been thoroughly substantiated since, that regeneration of pus-ridden joints and restoration of function are best accomplished by early evacuation and motion.

Motion of an infected joint should not create muscle spasm. It should be painless and free of the fear of pain, and there should be no discomfort

in the joint after the patient returns to bed. The use of the salt pool satisfies all these requirements, and these requirements are especially important when treating children. Motion in the water mechanically cleans away the infection, and because the water is hypertonic, there exists an osmotic pressure between this fluid and the body fluids, so that drainage is encouraged and accelerated from the innermost depths of the wound.

The salt concentration of the water in the pool is between 6 and 7 per cent, approximately the same strength as sea water. At this concentration the water sterilizes itself and cultures have always been negative. The temperature of the pool is maintained at about 96 degrees and the treatment lasts about thirty minutes. The floor of the pool should be sloping so that weight bearing on an infected joint can be gradually increased. As you know, the weight of the body standing in water is the weight of the body above the water line.

In this series there were eight cases of suppurative arthritis without bone involvement. In five the infection was in the knee, two in the hip, and one in the ankle. The average time required for healing was two and eight-tenths months, and complete motion was restored in every case in an average of five months.

In these cases the joint is incised widely and irrigated with several gallons of warm normal saline solution. The part is splinted for two or three days, and then the patient is put in the salt pool daily.

From these cases, and from the reports of other surgeons, it seems definitely established that acute joint infections, especially in children, respond well to early drainage and motion. By all odds, the best and most painless way to carry out this motion is by means of the salt pool.

ACUTE OSTEOMYELITIS WITH SUPPURATION OF THE ADJACENT JOINT

We will now consider those cases of osteomyelitis involving the ends of long bones, and in which there is an accompanying suppurative arthritis.

With this type of case it has been our routine to do a wide saucerization of the bone, removing

TABLE 3.—Acute Osteomyelitis in Close Proximity to Joints

as much of the diseased bone as possible, and pack the wound lightly with vaseline gauze as in the Orr treatment. The joint is also opened and irrigated. A plaster cast or spica is applied, depending on the bone involved.

The cast is removed in four to six weeks, which is about the time the first change of cast is made in the Orr treatment. A splint is applied and daily pool treatment started.

While motion at this early stage would seem a violation of the principle of rest, still the motion permitted in the pool is not such a violation of this tenet, as might be presumed. The buoyancy of the salt water, removing the gravity load, permits motion without pain or muscle spasm, and the part is splinted between treatments or even during treatment within the first week or so. Almost without exception the patient will state that the extremity feels better after his pool treatment.

There is another advantage of this form of treatment, especially in older patients. Remaining idle in bed for months in an ill-smelling cast does not appeal to some patients, particularly the more fastidious. In the pool the patient can daily watch the improvement of motion in the stiff joints and can see the wounds become smaller and cleaner. Certainly, a psychic appeal that is more than imaginary.

In this series there were twelve cases in which there was an osteomyelitis with suppuration of the adjoining joint. The return of motion in such cases, naturally, is not as great as in those in which there is no bone involvement.

The hip and ankle show more tendency to heal with motion while the knee and elbow have greater tendency to heal with ankylosis.

In the six hip cases, there was complete return of motion in two, and ankylosis in one; and in the remaining three the end-result was motion, varying from one-half to two-thirds normal.

In the three knee cases, one had a return of motion two-thirds of normal, and the other two ended in complete bony ankylosis; but it is only fair to state that one of these patients came to surgery late, and after there was considerable joint

dissolution and bone destruction in both the lower end of the femur and the upper end of the tibia. In such cases, experience has shown that joint motion is doomed, and it is better to proceed with the Orr treatment rather than attempting to gain motion.

There were two ankle cases. In one there was complete return of motion, and in the other the range of motion was one-third normal.

One elbow case resulted in complete fusion.

In those cases in which there is an osteomyelitis of the head and neck of the femur with a purulent empyema of the hip joint, the leg is immobilized for several months in plaster before pool treatment is started. In these hips the head of the femur usually becomes a sequestrum which requires surgical removal. Maintaining the remains of the neck in the acetabulum is the problem of first consideration. Adequate motion will develop later; and if one is successful in preventing the neck dislocating upward, a good stable hip will result that will stand up under ordinary use, and usually with motion of at least half-normal range.

OSTEOMYELITIS IN WHICH THE DISEASE PROCESS CLOSELY ENCLOSES UPON JOINT STRUCTURE

We come now to the third type of case in which the salt pool treatment is especially useful. These are the cases in which the osteomyelitic process, while not involving the joint proper, yet lies in very close approximation to the joint, involving at times the epiphyseal plate.

Some joints, like the elbow, but particularly the knee, tend to heal with considerable restriction of motion if they are long immobilized. Drainage for months about the knee, especially from the distal end of the femur, causes a plastering down of the vasti and rectus femoris muscles to the femur, and with this there occurs a thickening and shortening of the capsule of the knee, a condition which is aggravated by immobilization and minimized by early motion.

In this series there was an osteomyelitis near the ends of ten of the long bones, the diseased process being in close approximation to thirteen joints.

Since the joint itself was not involved, naturally, a greater return of motion could be expected than in the series described just above.

Of the thirteen joints, there was complete return of motion in seven, and in the other six the residual motion averaged about one-half normal.

I do not wish to give the impression that the salt pool has solved the problem of the treatment of osteomyelitis and suppurative joints, but I am convinced that in the selected type of cases as above described, it will give an end-result that cannot be duplicated by other methods.

SUMMARY

1. Thirty cases of acute suppurative arthritis and osteomyelitis with joint involvement, treated by surgical drainage followed by early motion in the salt-water pool, are presented.

2. In the eight acute suppurative arthritis cases without bone involvement, there was complete return of motion in all cases in an average of five months' time.

3. In the twenty-two cases of osteomyelitis with concurrent purulent infection of the neighboring joint and osteomyelitis closely encroaching upon joint structure, there was a gratifying return of joint motion in most instances.

4. The salt-pool treatment permits early motion without muscle spasm, pain or the fear of pain, and thus does not violate the principle of rest that is so essential in the treatment of any infection.

5. Motion of joints in the salt water not only mechanically washes away the pus, but, because it is a hypertonic solution, there is an osmosis outward of the tissue fluids which causes a thorough cleansing of the wound from its innermost depths.

3523 West Twelfth Street.

DISCUSSION

FRANCIS M. MCKEEVER, M. D. (1136 West Sixth Street, Los Angeles).—Doctor Brockway's statistics are very impressive. Particularly striking are his results with those patients in whom a primary osteomyelitis has ruptured into a joint.

The acute suppurative arthritis in which only synovial membrane is infected, with timely adequate drainage as a rule recovers sufficient motion so that no marked permanent disability results. The joint infected by the extension of an osteomyelitis through its articular cartilage is a much more discouraging situation which, altogether too often culminates in a complete ankylosis or a few degrees of painful, useless motion after a long exhaustive illness.

Doctor Brockway has mentioned adequate drainage of both the infected bone focus and of the joint. He has stressed early mobilization in a hypertonic saline medium.

The percentage of recovery of motion which he has mentioned is indeed excellent, and certainly warrants consideration of the saline pool as a valuable adjunct in the postoperative treatment of this type of case.

I feel, however, that a little more emphasis should be laid on the early diagnosis of the extension of the infection into the joint cavity, and the timely dual drainage of both the infected bone and the invaded joint, if articular cartilage is to be saved from the ravages of the products of inflammation.

FREDERIC C. BOST, M. D. (384 Post Street, San Francisco).—Doctor Brockway's paper is of real value. He has demonstrated by his splendid results the efficacy of hypertonic saline baths. No group of cases cause us more concern than those with which Doctor Brockway's paper has dealt, and any method of treatment that offers such hopeful progress is most welcome to all of us.

The physiologic basis for hypertonic saline baths to me seems a most logical one. The end-results, here presented, give clinical proof to this point. The physical side of this treatment might at first seem to make it impractical to most of us. However, all that is necessary is a bathtub, warm water and a sack of salt, and certainly we can all provide such accessories.

Since learning of Doctor Brockway's work, I have had the opportunity to use the salt-water treatment in several cases, and I can attest to the validity of his statements concerning the improvement in general condition, the relief from pain, and the marked enthusiasm on the part of the patient so treated. The rapidity with which dirty, sluggish wounds take on new life and cleanliness is remarkable. Limited use of this form of therapy will, I believe, serve to convince most of us that there is no better method for treating a septic joint.

We have all seen osteomyelitis, either with or without joint involvement, progress favorably for a limited period of time only to reach a stage of extreme sluggishness, which usually bespeaks a long and discouraging period of

chronicity. Doctor Brockway's method of handling these cases by the use of stimulating saline baths is to me a most excellent one.

~

SAMUEL S. MATHEW, M.D. (1913 Wilshire Medical Building, Los Angeles).—Doctor Brockway's results in the treatment of suppurative arthritis without bone involvement, by means of salt water pool treatment, are indeed gratifying. Just what part the pool treatment itself played in these excellent results is, however, hard to estimate. It has been my feeling that the prognosis for return of motion in an involved joint depends, to a great extent, on the organism present and what destruction has already taken place in reference to the articular cartilage. We often see, particularly in children, those cases in which the knee is swollen, with moderate amount of local heat, and associated with but little constitutional reaction. On incising such joints and thoroughly washing them out with large quantities of normal warm saline solution, the prognosis is good for full return of motion, the motion itself being started as the local symptoms subside. Then there are such cases where the invading organism is far more destructive and there has been a greater change in the joint, primarily due to delayed drainage. Our prognosis here is poor for return of normal function, regardless of our after-care. I have always felt that in either case active motion should not be started until local symptoms have subsided, because we are dealing with a diseased joint which should be kept at rest during its acute stage. Doctor Brockway has suggested an easy method of starting early motion by pool treatment, but he has emphasized that such early motion should be done without causing muscle spasm or pain. What importance we can place upon the use of salt water in such pool treatment I cannot state, because I feel that motion should not be started until, as I have said, the disease process has quieted down sufficiently.

CAN THE STATE EXAMINE PEOPLE ENTERING THE STATE WHO MAY BE SUSPECTED OF HAVING AN INFECTIOUS DISEASE?

OPINION OF THE ATTORNEY-GENERAL OF CALIFORNIA: IN RESPONSE TO REQUEST FROM
STATE BOARD OF HEALTH

In the January issue of CALIFORNIA AND WESTERN MEDICINE, editorial comment was made on "Indigent Camps in California: A New and Pressing Problem." (See page 2 of January CALIFORNIA AND WESTERN MEDICINE and also comment in this number, on page 146.)

The opinion rendered by Attorney-General U. S. Webb and Deputy Attorney-General Leon French contains much general and specific information of interest to members of the medical profession, and is, therefore, printed in full.

STATE OF CALIFORNIA
LEGAL DEPARTMENT

San Francisco, February 10, 1937.

Honorable Walter M. Dickie
Director, Department of Public Health
San Francisco, California

Dear Sir:

I have before me your communication under date of October 27, 1936, which is as follows:

It has been estimated that during the last two years somewhere in the neighborhood of 200,000 itinerant people have moved into California from the middle-western states and are now located in itinerant camps and government resettlement camps in the State of California. Many of these people are suffering from infectious diseases, namely, tuberculosis, trachoma, dysentery, typhoid fever, etc., all of which are a menace to the people of the State of California, for the reason that these migratory people are not entitled to institutional nor medical care

in the counties in which they are located, because of lack of residence.

In order that this condition may not be continued indefinitely, I would respectfully request the following opinion: Does the State Department of Public Health have the right under the law to examine people entering the State who may be suspected of having an infectious disease? If they have not sufficient funds to provide proper institutional or hospital care, can they be denied permission to enter the State?

There is on the statutes, as you know, "an Act to prevent introduction of contagious diseases into the State," approved March 15, 1883, but this refers only to train service, I believe.

As the questions which you submit are of major importance not only to the people of the State of California but also to the individuals coming to the State of California from other states, such questions have been given very careful and detailed consideration, particularly in view of the fact that, so far as the reports indicate, these questions have not received a definite determination by any court of last resort in this state. The question of exclusion was, however, considered in the case of *State vs. S. S. "Constitution,"* 42 Cal. 578, to which reference is hereafter made.

Perhaps the most enlightening cases to be found upon the subject of your communication are the so-called "Passenger Cases," decided by the Supreme Court of the United States at the January term in 1849 and reported in the seventh volume of Howard's Reports (48 U. S.) at page 283. The Passenger Cases were two kindred cases argued together before the United States Supreme Court, entitled, respectively, *Norris vs. The City of Boston* and *Smith vs. Turner*. They involved acts of the State of Massachusetts and the State of New York, respectively, relating particularly to the admission within their boundaries of passengers arriving by water at the ports thereof.

Each of the Passenger Cases was argued no less than three times before the Supreme Court of the United States, finally resulting in a decision by a bare majority of the nine justices declaring both the act of the State of Massachusetts and that of the State of New York unconstitutional and, therefore, void because of imposing a burden or regulation upon "commerce with foreign nations, and among the several states, . . ."

(Article I, Section 8, United States Constitution.)

However, in spite of such full argument and careful and lengthy consideration, there was no opinion of the court, as a court, filed in either of these cases. Each of the nine justices, with the exception of Mr. Justice Nelson, filed a lengthy opinion, and Mr. Justice Nelson expressly concurred not only in the conclusions but in the grounds and principles set forth at length in the dissenting opinion of Mr. Chief Justice Taney.

Throughout the report of these cases—covering some 290 pages—are found many and repeated expressions, both in the arguments and in nearly all of the opinions, expressly setting forth and maintaining the right of a state, under its retained police power, to exclude from its boundaries persons arriving thereat from either foreign countries or sister states within the Union where such exclusion was clearly based upon the retained police power and was clearly for the purpose of guarding against the introduction of any thing or person which might corrupt the morals or endanger the health or lives of the citizens of the excluding state.

Upon this principle the report of the "Passenger Cases," *supra*, indicates that every one of the eminent counsel engaged in the argument thereof, as well as every one of the nine justices of the Supreme Court of the United States, concurred.

A few of the many statements found in the opinions of the several justices, and which appear most clearly and definitely in point, will be quoted. For example: Mr. Justice McLean said (page 400):

In giving the commercial power to Congress, the States did not part with that power of self-preservation which must be inherent in every organized community. They may guard against the introduction of anything which may corrupt the morals, or endanger the health or lives of their citizens. Quarantine or health laws have been passed by the states, and regulations of police for their protection and welfare.

Mr. Chief Justice Taney, in his opinion (page 467), said:

I think it, therefore, to be very clear, both upon principle and the authority of adjudged cases, that the several states have a right to remove from among their people, and to prevent from entering the state, any person, or class or description of persons, whom it may deem dangerous or injurious to the interests and welfare of its citizens; and that the state has the exclusive right to determine, in its sound discretion, whether the danger does or does not exist, free from the control of the general government.

Mr. Justice Woodbury, in his opinion (page 525), stated:

The best writers on national law, as well as our own decisions, show that this power of excluding emigrants exists in all states which are sovereign.

He further said (page 528):

Again, considering the power to forbid as existing absolutely in a state, it is for the state where the power resides to decide on what is sufficient cause for it, whether municipal or economical, sickness or crime; as, for example, danger of pauperism, danger to health, danger to morals, danger to property, danger to public principles by revolutions and change of government, or danger to religion.

As to the extension of this right of exclusion to those coming from another state within the Union, Mr. Justice Woodbury further stated (page 529):

As a question of international law, also, they could do the same as to the citizens of other states, if not prevented by other clauses in the Constitution reserving to them certain rights over the whole Union, and which probably protect them from any legislation which does not at least press as hard on their own citizens as on those of other states.

Upon this same point he further said (page 543):

The states have been in the constant habit of prohibiting the introduction of paupers, convicts, free blacks, and persons sick with contagious diseases, no less than slaves; and this from neighboring states as well as from abroad.

Upon this same question, Mr. Justice Mathews of the United States Supreme Court, in delivering the opinion of the court in the case of *Bowman vs. Chicago, etc., Ry. Co.*, 125 U. S. 465, at page 492, quoted with approval from the opinion in the case of *Railroad Co. vs. Husen*, 95 U. S. 465, 471, where it was said:

It may also be admitted, . . . that the police power of a state justifies the adoption of precautionary measures against social evils. Under it a state may legislate to prevent the spread of crime, or pauperism, or disturbance of the peace. It may exclude from its limits convicts, paupers, idiots, and lunatics, and persons likely to become a public charge, as well as persons afflicted by contagious or infectious diseases; a right founded, as intimated in *The Passenger Cases*, 7 How. 283, by Mr. Justice Grier, in the sacred law of self-defense. . . .

Reference should also be made to the case of *Jacobson vs. Massachusetts*, 197 U. S. 11, decided in 1905, in which the Supreme Court of the United States had under consideration questions involving the validity, under the Constitution of the United States, of certain provisions of the statutes of Massachusetts relating to vaccination.

Mr. Justice Harlan, delivering the opinion of the court, said in part (page 28, *et seq.*):

In *Railroad Company vs. Husen*, 95 U. S. 465, 471-473, this court recognized the right of a state to pass sanitary laws, laws for the protection of life, liberty, health, or property within its limits, laws to prevent persons and animals suffering under contagious or infectious diseases, or convicts, from coming within its borders.

See, also, *State ex rel McBride vs. Superior Court* (Wash.), 174 Pac. 973.

That the right of inspection and exclusion extends not only to those presenting themselves at the borders of a state in the course of travel from a foreign port, but likewise to those so presenting themselves by travel from one of the states of the Union to another thereof, seems clearly supported not only by reason, but by authority. In fact it would appear that the only limitation upon such an authorized exclusion is that the provision of law governing the same must not be more burdensome upon the citizens of a sister state seeking to enter the boundaries of

the excluding state than they are upon the citizens of the excluding state itself who have been beyond its borders and seek to reënter; in other words, the same rule must apply to all.

When the law operates alike on all persons and property similarly situated, equal protection of the law cannot be said to have been denied.

Sutherland's Notes on the Constitution, page 729.

It would further appear that this police power of the state should only be exercised when public necessity demands it within reasonable and fair apprehension, and not upon mere suspicion.

29 Corpus Juris, page 253.

In the case of *State vs. S. S. "Constitution," supra*, the Supreme Court of the State of California had before it a proceeding *in rem*, seeking to enforce a lien upon the vessel because of the failure of the owner or consignee thereof to give a required bond or pay requisite commutation money in lieu thereof in connection with certain aliens landed at the port of San Francisco under the provisions of an Act approved May 2, 1852 (Statutes 1852, page 78), and amended by an Act of April 2, 1853 (Statutes 1853, page 71). Mr. Justice Crockett, in delivering the opinion of the court in that case, said in part (page 584):

In considering the grave question here presented, it is to be observed, *in limine*, that whatever may have been the real purpose of the statute, its ostensible purpose was to provide police and sanitary regulations, to prevent the people of this State from becoming chargeable with the support and maintenance of persons imported from foreign countries, who either then were, or were soon after, liable to become a public charge. If it were conceded that this was the real purpose of the statute, and that its provisions are reasonably adapted, and were intended to secure this result, and this only, there would be an end to the argument; for in all the numerous adjudications which have been had in respect to the power of the several states to interfere with commerce under the clauses of the Constitution above referred to, it has never been doubted that a state has the power, by proper police and sanitary regulations, to exclude from its limits paupers, vagabonds, and criminals, or sick, diseased, infirm, and disabled persons, who were liable to become a public charge, or to admit them only on such terms as would prevent the State from being burdened with their support. To surrender this power would be to abandon one of the highest prerogatives of local self-government, one of the chief functions of which is to preserve the public health and to repress crime. . . . The power to make police or sanitary regulations prescribing the terms on which certain classes of persons shall be admitted into this State, necessarily includes the power to exclude them altogether if they fail to comply with the prescribed conditions.

Section 14 of Article XX of the Constitution of the State of California provides:

The legislature shall provide, by law, for the maintenance and efficiency of a state board of health.

The foregoing mandate of the Constitution is complied with in the enactment of Sections 343, 368, 372 to 372g, inclusive, and 2978 to 2984, inclusive, of the Political Code.

Under the provisions of Section 2979 of the Political Code the State Board of Health—the predecessor in power and duty of the Department of Public Health—is expressly required to "examine into the causes of communicable diseases in man and domestic animals occurring or likely to occur in this state."

It is further provided that "it may quarantine or isolate, inspect and disinfect persons, animals, property and things of whatever nature, and houses, rooms, places, cities or localities, whenever in the judgment of said board or pending its meeting, whenever in the judgment of its executive officer such action shall be deemed necessary to protect or preserve the public health; . . ."

It is further provided in said section that "it may establish and maintain places of quarantine or isolation."

Section 2979 further provides:

It shall have general power of inspection, examination, quarantine and disinfection of persons, places and things, within the state, and for the purpose of conducting the same may appoint inspectors, who, under the direction of the board, shall be vested with like powers; provided that this Act shall in no wise conflict with the national quarantine laws.

By the same section authority is conferred "to adopt and enforce rules and regulations for the execution of its duties under this section. . . ."

By Section 2979a of the Political Code it is provided that when the State Board of Health or its secretary is informed as to the existence of certain contagious or infectious diseases (including those of tuberculosis, trachoma, dysentery, and typhoid fever, referred to in your communication) it or he "may thereupon take such measures as may be necessary to ascertain the nature of such disease and prevent the spread of such contagion, and to that end, said State Board of Health, or its secretary, may, if deemed proper, take possession or control of the body of any living person, or the corpse of a deceased person, and may direct and take such means as may be deemed expedient to arrest or prevent the further spread of such disease."

Penalties for crimes against public health and for failure to conform to rules, orders and regulations respecting quarantine or disinfection of persons, are provided by the Penal Code, and particularly by Section 377a thereof.

Sections 12 and 13 of the Act of March 23, 1907 (Stats. 1907, page 893, as amended; Act 6238 of Deering's General Laws, edition of 1931) impose upon every county health officer and every city and county, city or town board of health, or chief executive health officer thereof, the duty of carrying out the directions of the State Board of Health or its secretary, with respect to quarantine and disinfection.

The Act of March 15, 1883 (Statutes 1883, page 376; Act 6243 of Deering's General Laws, edition of 1931) is, as you state in your communication, applicable only to "railroad communication with other states," and can be given no application with regard to those traveling by other means of communication or transportation.

There are, of course, many other acts dealing generally with the health of the people of the State of California and the suppression and control of contagious and infectious diseases, but it is believed unnecessary to advert here to all thereof.

While from the foregoing it would appear clear that the health authorities of the State of California have the right to inspect at the borders those coming from other nations or states into the State of California, and, under the police power, to exclude from the State of California those found to be infected or contaminated with infectious or contagious diseases dangerous to the health of the people of the State of California, it must be remembered that such burdens must be imposed equally and impartially upon all persons so presenting themselves at the boundaries of the State of California for progress into the body of this state. Further than this, any such inspections should only be made or conducted by personnel trained and qualified therefor, and not by persons who are merely peace officers or who are untrained personnel.

A further limitation upon the power of exclusion must also be noted. That is fully and carefully set forth in the reported opinion in the case of *In re Arata*, 52 Cal. App. 380, where, at page 383, it is said:

That the health authorities possess the power to place under quarantine restrictions persons whom they have reasonable cause to believe are afflicted with infectious or contagious diseases coming within the definition set forth in Political Code, Section 2979a, as a general right, may not be questioned. It is equally true that in the exercise of this unusual power, which infringes upon the right of liberty of the individual, personal restraint can only be imposed where, under the facts as brought within the knowledge of the health authorities, *reasonable ground exists to support the belief* that the person is afflicted as claimed; and as to whether such order is justified will depend upon the facts of each individual case. Where a person so restrained of his or her liberty questions the power of the health authorities to impose such restraint, the burden is immediately upon the latter to justify by showing facts in support of the order. It might be proved, for instance, that the suspected person had been exposed to contagious or infectious influences that some person had contracted such disease from him or her, as the case might be. Such proof would furnish tangible ground for the belief that the person was afflicted as claimed. And we wish here to emphasize the proposition, which is unanswerable in law, that a mere suspicion, unsupported by

facts giving rise to reasonable or probable cause, will afford no justification at all for depriving persons of their liberty and subjecting them to virtual imprisonment under a purported order of quarantine.

The provisions of the health laws and regulations must also be reasonable, although to be effective they must be prompt and summary. *County of Los Angeles vs. Spencer*, 126 Cal. 670, 673.

And while Section 2979a of the Political Code, *supra*, confers upon county and other health officers the right to take measures necessary to prevent the spread of disease, but does not confer upon such local health officers the right to take possession of the body of one so afflicted as it does in the case of the State Board of Health, yet nevertheless isolation of one afflicted with an infectious disease has been held to be a reasonable and proper measure to be enforced by local health authorities to prevent the increase and spread of such diseases.

In re Fisher, 74 Cal. App. 225;

In re Johnson, 40 Cal. App. 242.

For the foregoing reasons, and with the limitations set forth in connection therewith, your queries are answered in the affirmative.

Very truly yours,

U. S. WEBB, *Attorney-General*.

(Signed) By LEON FRENCH, *Deputy*.

THE LURE OF MEDICAL HISTORY†

DIPHTHERIA IN 1880: IN SISKIYOU COUNTY

By E. W. BATHURST, M.D.

Etna

IN 1877 I began practicing medicine in Sawyers Bar, Siskiyou County. This small town was dependent upon the near-by mines (placer and quartz) for its existence. Located upon a narrow strip of gravel deposit on one side of the North Fork of the Salmon River, the houses, stores, hotels, and saloons were strung along this strip of gravel for about a mile, the river some twenty to fifty feet below. As the center of the mining activities of the Salmon River section, the little town housed the wives and children of the miners engaged in the Black Bear, Klamath and quartz mines, or who stripped gravel deposits for the auriferous deposits, and was fairly prosperous. When you reached Sawyers Bar you had attained "the jumping off place," for there was no way of communicating with the outer world but by trails, over which pack-trains brought in merchandise (liquid and solid), together with our six-day mail service from Etna. In the winter, mail was transported on webbed snowshoes, a perilous job not unattended by fatalities. The nearest supply of drugs was in Etna, some twenty-six miles away, a two days' trip by mule-back, hence it behooved the Sawyers Bar medico to keep a stock of medicines on hand, particularly as there were no trained nurses, and the nearest consultant was at Etna; so at least the location taught self-reliance.

The mountainous country was well drained, the streams did not glide placidly over nearly level

†A Twenty-Five Years Ago column, made up of excerpts from the official journal of the California Medical Association of twenty-five years ago, is printed in each issue of CALIFORNIA AND WESTERN MEDICINE. The column is one of the regular features of the Miscellany department, and its page number will be found on the front cover.

bottoms, but hurried and scurried down the ravines to swell the North Fork of the Salmon which, in turn, joined the South Fork at the "Forks of the Salmon," when the stream of added volume wended its way to Somes Bar, blending its waters with the Klamath River. At that point, four rivers empty into the Klamath on the south side—Shasta, Scott, Salmon, and Trinity—and these drain a vast precipitous watershed. On the north side of the Klamath are numerous large creeks that empty into the main river—creeks that in summertime surpass the Los Angeles River. Fishing is good—mountain trout just after May 1 of each year—while later it is not so good. In the fall, well, we have steelheads and salmon, as the papers detail; also the largest fish hatchery in the State. So, come up after the first fall rains and enjoy our fishing.

THE DIPHTHERIA EPIDEMIC

But this does not describe a diphtheria epidemic as handled at and around Sawyers Bar in 1880. School was out, summer was in full swing, when I was called to see a child with diphtheria. The kindly neighbors sought to help the afflicted families, so the disease spread quickly; there was no quarantine, little segregation, the days were warm if not hot, the buildings not closely together, abundant good air and water, but the type of the disease was what my forebears termed "*Putrid sore throat*." Those afflicted with it positively stank, so I do not doubt that if George Washington had this type he either died of toxemia or phlebotomy—*quien sabe?* The fauces and nasal passages were thickly coated with a yellow, cream-colored, thick membrane; temperature not over 101 degrees, patient stolid, embarrassed breathing due to pharyngeal engorgement, and a horrible odor—so bad that, despite the liberal use of chlorid of lime and phenol, our only available disinfectants, it was impossible to stay in the room with the patient. I have correctly diagnosed this type of diphtheria before I entered a room merely by the odor. Some cases occurred at Black Bear Mine, some seven miles away, where one baby had an inflamed neck (intertrigo); this became infected, and despite local treatment plus internal medication, the toxemia proved fatal—a fact not to be wondered at, perhaps, since in this home, on a sidehill, high off the ground with nothing but posts to rest upon, the wind swept daily, and butter stored in a keg became contaminated and inedible.

A Welsh boy was treated. I had to have an old-time Cornish woman translate the Welsh language pertaining to the case to me. For about six weeks I did not go to bed, but laid down where I happened to be, on cot or lounge, to be called two hours later to go and visit new patients or revisit the older ones.

TREATMENT

The remedies used, aided by the pure mountain air and clear cold water, consisted principally of iron internally and application of Loeffler's solution locally; a typical treatment for a ten-year-old child being:

R Tincture of Ferri Chloridi 5ii
Glycerin flid. ʒiv

A teaspoonful was given every three hours without water, preceded by an initial dose of calomel, five grains. The throat was painted every time I got around to do it, using Loeffler's solution on a swab. A small amount of whisky was given, if indicated. The iron mixture, given undiluted, was to coat the fauces as well as combat the infection. I soon learned that if the iron turned the membrane black the patient got well, which happened with the majority, for out of the 110 cases only five died; so that with no skilled nurses, no antitoxin, I think the results were good. I know everyone coöperated and shared each other's sorrows.

Loeffler's solution contains 4 per cent ferric chlorid solution, so we weathered through the epidemic—houses and clothing aired and, as far as possible, disinfected. In later years I have wondered if a like treatment would be of service in serious diphtheritic infection to aid antitoxin in its work—there being with us only one case of laryngeal involvement.

CLINICAL NOTES AND CASE REPORTS

GAS-GANGRENE INFECTION OF THE UTERUS

By ALBERT H. NEWTON, M.D.

AND

ROY F. SCHLAPPI, M.D.

Yreka

GAS-GANGRENE infection is one of the most serious complications met with in modern surgery. A search through the available literature on the subject, involving the uterus, reveals the infection to be practically 100 per cent fatal. In dealing with this type of infection, one must be radical in surgical treatment and early radical removal of the internal genitalia, with massive doses of antitoxin, plus supportive treatment, will probably result in an occasional saving of human life.

REPORT OF CASE

We wish to report the successful cure of a gas-gangrene infection, involving the uterus of a three and one-half months pregnant woman, Mrs. L. M., married, age 26; occupation, housewife; American; white; para, two.

The above-named patient was brought to the Siskiyou County General Hospital at 6 p. m. February 23, 1935, with a complaint of chills, high fever, severe abdominal cramps and general malaise.

Past History.—Born in Utah. Lived in California nineteen years. Measles and mumps in childhood. Previous surgery: Curettment following childbirth, and perineal repair three years ago. Tonsillectomy several years ago. Husband living and well. Two children living and well, ages four and three. Cta.: Menses began at fourteen, every 28/5. No dysmenorrhea. Last normal period, November 6, 1934. Other systems essentially negative. Family history essentially negative.

Present Illness.—The patient's last normal menstrual period was in November, 1934. The patient was told, following an examination on or about December 25, 1934, that she was two months pregnant. On February 21, 1935,

the patient attempted to induce an abortion, using the following technique: She douched the vagina thoroughly, sterilized a piece of elm bark, six or eight inches in length, by dipping it in boiling water, wrapped the tip with cotton and inserted the instrument into the uterus by the vaginal route. The patient states that she fainted at this time, and upon revival she withdrew the foreign body. Bloody vaginal flow followed a few hours later, and on the following day she experienced severe abdominal cramps. On the morning of February 23 she began to have chills and fever. The abdominal cramps became more severe, and she was brought to the hospital at 6 p. m.

Examination and Surgical Procedures.—Examination revealed a medium-statured woman of twenty-six years, sobbing and crying with pain. Temperature was 104 degrees Fahrenheit. Pulse 160 per minute, regular, but of poor quality. Respiration was 20 per minute. The patient appeared quite toxic; the mucous membranes were extremely pale. The chest revealed no pathology. The abdomen was flat, with marked rigidity of the lower abdomen. Pelvic examination revealed an approximately three and one-half months fetus, partially expelled from the uterus into the vagina. The tissues of the fetus were macerated and gave an extremely foul odor. Much foul gas was expelled from the uterus, upon introducing a weighted speculum into the vagina. There were present in the canal of the cervix and on the fetus numerous one-half centimeter blebs containing serum and gas. Under gas anesthesia, the uterus was curetted free of its contents, including a placenta that was filled with small blebs containing serum and gas. This procedure was accompanied with considerable hemorrhage. Smears were taken from the fetus, placenta, and the cervical canal, at this time, and the vagina was then temporarily packed with sterile gauze. Laboratory report of the smears showed a pure strain of gas bacillus presenting the usual morphology. One therapeutic dose of polyanerobic serum (*B. welchii* 10,000 units, *B. sordellei* 50,000 M. L. D., *Vibrio septique* 10,000 units, and *edematiens* 50,000 M. L. D.) was administered intramuscularly, and 1,000 cubic centimeters of normal saline, containing 5 per cent glucose, was given subcutaneously. Blood count at this time was 2,700,000 red blood cells; hemoglobin, 50 per cent. Blood pressure was 90/30. Pulse 140 per minute, regular, poor volume. Blood donors were obtained, and 500 cubic centimeters of citrated whole blood, containing a second therapeutic dose of antitoxin, was administered intravenously. Following this, blood pressure rose to 110/60, pulse 120 per minute. The patient was transferred to surgery at 8 p. m., and under low spinal anesthesia a vaginal panhysterectomy was performed. The uterus, fallopian tubes, ovaries, including one inch of the uterine attachment of the broad ligament, were dissected en masse (in one piece), the dissection being carried laterally quite widely into the edematous broad ligaments, round ligaments, and uterosacral ligaments. The peritoneum was then closed with a purse-string suture of plain catgut, the divided ends of the round ligaments, broad ligaments, and uterosacral ligaments were sutured together, slinging the same beneath the bladder. The fascial planes were then united with chromic catgut and silkworm gut sutures. The patient withstood the operation satisfactorily, pulse remaining 120 to 130, blood pressure 110/60. Examination of the pathologic specimen revealed the uterus, tubes, ovaries, and parametrial tissue to be filled with blood and lymph. The cervix was markedly congested with lymph.

Four hours following surgery, a third therapeutic dose of polyanerobic antitoxin was administered intramuscularly, and at 9 a. m. on the following morning a fourth therapeutic dose of antitoxin was administered, and 300 cubic centimeters of whole citrated blood was given intravenously.

Postoperative Course.—The patient ran a mild septic fever for four days, postoperative, with pulse ranging from 100 to 120 per minute, following which the temperature curve approached the normal, with pulse coming down to 70 to 80. The patient developed some serum sickness five days postoperative, which was controlled with adrenalin. Physical examination on March 5, 1935, revealed the following: The patient appeared rather anemic; had no system complaints; lung fields were clear; heart

rate was 64, regular. Blood pressure was 120/80. Abdomen was soft and flat. Some tenderness to deep palpation in the lower abdomen. Pelvic examination revealed the wound in the vaginal vault to be healed by primary union. Silkworm gut sutures were removed.

Laboratory Report.—Urine was negative. Red blood cells, 3,700,000; white blood cells, 8,800; normal differential. Blood Wassermann was negative.

Report of examination of slides taken at the time the patient was curetted, from the Department of Public Health, State of California, Bureau of Laboratories, is as follows: "We received the slides and examined them, after staining by Gram's method. They showed numerous Gram-positive bacilli, having the usual morphology of organisms of the gas-gangrene group. (Signed) W. H. Kellogg, M. D., Chief of the Bureau of Laboratories."

The patient was discharged cured on March 8, 1935.

COMMENT

Successful cure of gas-gangrene infection is reported: Case, a three and one-half months' pregnant uterus, with radical vaginal panhysterectomy; plus 40,000 units *B. welchii*, 200,000 M. L. D. *B. sordellei*, 40,000 units *vibrio septique*, and 200,000 M. L. D. *edematiens*, and 800 cubic centimeters of whole citrated blood, and 3,000 cubic centimeters of normal saline with 5 per cent glucose; the antitoxin, blood and fluid being administered over a period of twelve hours, preceding and following surgery.

PAIN ALLEVIATION IN INOPERABLE MALIGNANCY

By H. S. PENN, M.D.
Los Angeles

IN a recent communication¹ Doctors Walter B. Coffey and John D. Humber described their experience with an aqueous suprarenal extract in the treatment of malignancy. I wish to refer to that part of the paper dealing with the pain-alleviating properties ascribed to the extract, and its action on the blood cholesterol.

During the past four years I have used, among other preparations, aqueous extracts of the suprarenal, thyroid, and spleen in cases of inoperable malignancy. These were prepared by extraction of the ground-fresh tissue in normal saline, made slightly alkaline with NaOH. After a twenty-four hour extraction, a precipitate was effected by adding .2 per cent acetic acid, or acetone. In case of the suprarenal gland, the solution was first treated with ammonium hydroxid (to precipitate out medullary products) filtered and then followed by .2 per cent acetic acid. The protein mass consisting chiefly of globulin and allied substances was centrifuged, dissolved in normal saline in 1:100 ratio, brought up to a pH 7.5 and filtered through a Seitz filter. To this filtrate .4 per cent tricresol was added. It was noteworthy that, although these preparations came from three different sources, the pain-alleviating property was common to all. The action of some of these preparations was more pronounced than that produced by opiates. On several occasions pain disappeared within a few minutes after injection, and was for as long as from four to six hours.

A plausible explanation of this phenomenon may rest on the fact that the globulins and allied substances are combined with the phosphatids.² It is conceivable that the latter may be responsible for this palliative action. This contention is based on the results obtained in a limited number of cases of inoperable malignancy, where phospholipin emulsion was used. Its pain-alleviating action was quite pronounced. Where such palliation did occur, the patient was free from pain from twenty-four to forty-eight hours. It would seem, then, that this attribute of pain alleviation cannot be made a specific property of the suprarenal extract.

Concerning the effect of the suprarenal extract on blood cholesterol it was found by a number of investigators³ that feeding whole thyroid, KI, and certain fractions of the phosphatids produced the same result. In addition I had an occasion to observe in a limited number of trials, both animal and human, that, after repeated injections of the suprarenal extract, the blood cholesterol returned to its original level within ten to fourteen days. This manifestation is also observed after a prolonged use of certain phospholipins.

Incidentally, I wish to state that at no time have I noted definite retrogressive changes in malignant growths after the administration of the glandular aqueous extracts, either in humans or in experimental animals (Flexner Jubling rat carcinoma).

BLADDER IRRITABILITY DUE TO CARELESS OPERATIVE TECHNIQUE

By H. VERRILL FINDLAY, M.D.
Santa Barbara

I WISH to cite two recent experiences which may serve as a timely warning to those who are performing surgery in regions adjacent to the bladder. Symptoms of disturbed urination following various types of pelvic surgery, especially in the female, are not uncommon. Fortunately, the vast majority disappear in a brief time after appropriate simple treatments are given. There is, however, a small group of patients whose persistent, annoying bladder symptoms make their life most miserable. They are frequently passed between gynecologist and urologist without receiving any real or lasting benefit. Only those of us who have had patients of this type can know the misery which they endure and the futility of our efforts to relieve them.

The majority of these patients have their post-operative symptoms because of ill-chosen or poorly performed surgery. Under the former grouping, one might mention the many women whose urinary

frequency had been unaffected by a perineal repair and uterine suspension because the symptoms were entirely due to a contracted bladder resulting from a chronic cystitis of many years' duration.

I wish to comment particularly, because of two patients whom I have recently seen, on the individuals having persistent bladder symptoms due to faulty operative technique: One had been operated upon by a urologist and the other by a gynecologist.

REPORT OF CASES

CASE 1.—The first patient, a woman of fifty-five, came to me because of "severe bladder cramps," which would occur periodically and persist intermittently for as long as three days. She could determine no exciting factor except constipation. Her symptoms began some three months following an exploratory laparotomy ten years previously. She thought her uterus had been removed at that time. Examination of her pelvis revealed a firm, slightly tender mass, which might have been either an atrophic uterus or a generous cervical stump with numerous adhesions. A catheterized urine specimen showed no pus. When the bladder was filled with 200 cubic centimeters of sterile solution she would complain of its aching, but did not have any spasmodic voiding. At cystoscopy the bladder appeared normal.

This patient continued to be miserable and, at her request, her abdomen was explored. At the previous operation a hysterectomy had been done, and the stump of the cervix had become fixed rather high on the bladder wall, toward the fundus. I could not determine whether it had been fixed there originally or had become attached by adhesions. This cervical attachment was so situated that, as the bladder filled, it seriously interfered with the normal expansion of that organ, and was undoubtedly the cause of her symptoms. When this attachment was freed, the cervix descended and the bladder was able to expand normally.

• • •

CASE 2.—The second patient, a seventy-year-old woman, had a desire to void when lying down and, on answering the urge, could produce only a small quantity of urine. The symptoms were scarcely noticeable when standing. She had had a partial excision of the bladder for a "chronic ulcer" some twelve years previously, and the present symptoms dated from that time. Cystoscopy revealed nothing abnormal, except a mild trigonitis. I performed a peritoneoscopy with the Ruddock peritoneoscope, and found that the uterus lay in a horizontal position, and was firmly attached to the entire dome of the bladder. It was fixed so that the fundus of the uterus almost touched the symphysis. When the bladder was filled the uterus kept approximately this same position. When the patient was placed in a Trendelenburg position, with the bladder empty, the uterus could be seen to have tilted slightly backward, producing some tension on the bladder. With the uterus in this position, the patient had a painful desire to void, but when encouraged to do so, could not. When she was replaced in the horizontal position the uterus was seen to fall forward, and the patient was immediately relieved of her symptoms.

COMMENT

This first woman had urinary symptoms because of faulty fixation of the cervical stump, following hysterectomy. The second patient had her symptoms because the uterus had apparently been used to close or reinforce a defect in the dome of the bladder.

I cite these two experiences to show the misery which patients may be forced to endure because of faulty or careless surgery done in the pelvis. Though the bladder is an elastic organ capable of remarkable regeneration and adaptation, it should, none the less, be treated with proper surgical consideration by both gynecologist and urologist.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

DERMATITIS VENENATA

I. ETIOLOGY

SAMUEL AYRES, JR., M.D. (2007 Wilshire Boulevard, Los Angeles).—The old term "dermatitis venenata," signifying "an irritation of the skin due to a poison," is gradually being replaced by the more accurate designation, contact dermatitis, or an eruption due to contact with some irritating substance, not necessarily a poison in the ordinary sense. It should be clearly understood at the outset that contact dermatitis, while sometimes spoken of as "contact allergy," is in no way related to atopic allergy, which is an inherited tendency to become sensitized to foreign proteins in foods, pollens, epidermal derivatives, etc., and manifests itself as the eczema-asthma-hay fever complex. While dermatitis venenata often appears as an eczematous type of eruption, it has many points of difference from an eczema of the inherited atopic allergy type. So far as known, dermatitis venenata, or contact dermatitis, is not associated with asthma or hay fever any more frequently than the law of chance would account for, it is not inherited, and any normal non-sensitive individual can become sensitive under certain circumstances. The fact that an individual has been in frequent contact with a certain substance for many years without suffering inconvenience is no argument against the present eruption being due to that substance. The mechanism by which a person suddenly develops a sensitivity to a substance to which he was formerly immune is not known.

A list of the substances which have been proved at one time or another to have been actually responsible for cases of contact dermatitis is almost inexhaustible, and no substance, however commonplace or innocuous appearing, should be overlooked in considering the cause of a given case of dermatitis. There is probably not another field of medicine in which the amateur detective has a better opportunity of proving his skill. An exhaustive cross-examination and a close scrutiny of all available evidence, with attention to the minutest detail, will often uncover clues which will point to the offending agent.

Not so many years ago, in the days before the employment of patch tests, the known causes of dermatitis venenata were relatively few. Poison ivy in the East and the Middle West, and poison oak on the Pacific Coast, were the principal known causes of the disorder, and still rank high as etiologic agents. Fixed oils, lobinol in the case of poison oak and toxicodendrol in the case of poison ivy, are the offending substances, and actual contact with the plant or some product thereof is necessary for the development of a dermatitis. The pollen of these plants, however, is capable of

producing the eruption, so that it would be possible for a person to develop an attack of poison oak without actually touching the plant itself. Dermatitis is also reported to have resulted from contact with smoke from a bonfire in which the plant was burning.

It is believed that most cases of dermatitis due to contact with plants are caused by an oil. While poison oak and poison ivy are the greatest offenders, other plants are relatively frequent trouble makers, while still others only on rare occasions produce a dermatitis. *Primula obconica*, the lovely pink primrose, has achieved a certain reputation for bad behavior. The oil of ragweed or other weed pollen may cause a severe contact dermatitis of the face, while the same individual may be entirely unaffected by the protein fraction and suffers no inconvenience from asthma or hay fever, which are manifestations of protein sensitivity. In California some of the plants which have been known to have caused contact eruptions are lantana, English ivy, geum, wigandia, geranium, chrysanthemum, snapdragon, etc. Among the weeds, Western, slender and false ragweed, and camomile are well-known offenders, especially the former. Cases of dermatitis from various kinds of wood, such as redwood, pine, mahogany, ebony, etc., have been reported. We have seen dermatitis of the fingers and hands from squeezing oranges and lemons, and caused by an oil in the peeling.

The causes of dermatitis venenata among various trades and industries are as varied and as changing as the industrial processes themselves. An excellent reference book for eruptions of this type is R. Prosser White's "Dermatogoses," or industrial dermatoses. It would be far beyond the scope of this paper adequately to discuss the causes of dermatitis in the industrial field. Oils, paints, dyes, lacquers, lime, metals, leather, and chemicals of all sorts and descriptions must be considered.

Some of these substances occur sufficiently often in fields of general activity to merit some discussion. Among the metals, nickel is probably the greatest offender; and inasmuch as nickel is contained as an alloy in "white gold," many cases of nickel dermatitis have been traced to wrist-watches, rings, eyeglass frames, hair curlers, metal garter pieces, etc. Metal polishes are almost universally irritating, and frequent contact with them would be likely to irritate even a relatively non-sensitive skin.

We have observed several interesting cases of dermatitis due to leather in various locations: the forehead from hat-band and head-mirror leather, the buttock and thigh from a leather wallet carried in the hip pocket, feet from shoe leather. Both dyes and chemicals employed in processing the leather can cause trouble.

We have encountered cases of dermatitis due to paints, dyes, lacquers, etc., of non-industrial origin, as follows: "toilet-seat dermatitis" due to the finish on a toilet seat; lacquer dermatitis from contact with lacquered wood such as Mah Jongg sets; dermatitis from dye in clothing, hair dye, etc.; eruptions of the hands and sometimes of the face from printer's ink on ordinary newspaper or rotogravure supplements.

Irritation from chemicals used in photographic developing illustrate how hobbies must be investigated as well as trades and industries.

Cosmetics are responsible for many eruptions, especially in women, and again let it be emphasized that a cosmetic which a patient has used for years is just as likely to be the offending substance as a new cosmetic. From a medico-legal point of view it is well to remember that unless a given cosmetic causes an unwarranted number of reactions to patch tests in normal individuals, an infrequent eruption due to the cosmetic is to be regarded in the same light as a personal idiosyncrasy to any other substance and should not carry any implication of negligence on the part of the manufacturer. But it is the rare case of sensitivity which the physician is called upon to recognize. Any type of cosmetic may be responsible, and the list to be investigated should include hair dyes, hair-waving solutions, hair tonics, shampoos, rinses, face powders, cold creams, lotions, shaving lotions, shaving soaps and creams, astringents, bleaches, rouges, lip sticks, eye shadows, eyebrow pencils, mascara, perfumes, and dentifrices. Tooth paste may or may not be considered a cosmetic, but certain brands, especially those containing hexyl-resorcinol (S. T. 37), have been reported as causing an irritation of the lips and sometimes even of the fingers. Perfume dabbed on the neck or behind the ear may not cause a dermatitis until acted upon by the sunlight.

Many other medicinal or semi-medicinal substances which are used externally have been known to cause dermatitis. The following may be included in this list: mouth washes, gargles, nose drops (ephedrin, essential oils, etc.), eye drops, liniments, massage oils (oil of eucalyptus, camphor), alcohol rubs, excessive bathing (especially in cool, dry weather in elderly people), medicated soaps, finger-nail polishes and polish removers, douches and contraceptives, many proprietary salves and lotions, especially those containing mercury, butescin picrate ointment, ointments containing various types of local anesthetics, etc.

Physicians and dentists developing eczematous eruptions of the hands should consider local irritation from novocain, antiseptic solutions, rubber gloves and glove powders.

Urine retained in contact with the skin may cause the so-called diaper dermatitis of infants which is believed to be due to a decomposition of the urine by skin or fecal bacteria with the liberation of ammonia and resultant irritation. A similar process affecting the glans penis may be observed occasionally in men who, after urination, allow a drop of urine to be retained under the foreskin.

Wool clothing, silk, horse hair or dander and other epidermal derivatives may cause dermatitis, either by contact (in which it is a true case of contact dermatitis), or by inhalation, resulting in an atopic sensitivity with a clinical reaction manifesting itself either as eczema, asthma, or hay fever.

While yeasts, molds, fungi and other infectious agents usually produce their effects by parasitic action on the skin, or by absorption of their toxic products (so-called "allergy of infection"), with the development of "id" eruptions, cases of contact sensitivity to yeasts and fungi have been reported in which strongly positive patch tests were obtained to kill extracts of the organisms.

Finally, two cases may be briefly cited to illustrate totally unsuspected sources of irritation. One patient, a girl about sixteen years old, presented a vesiculo-crusted eruption of the face which at first suggested a milium type of impetigo. Finally satisfying ourselves that the condition was noninfectious, we began a series of patch tests with cosmetics. Only the adhesive tape used in making the patch tests caused reactions, and these were severe and similar to the eruption of the face. Testing separately the ingredients of adhesive tape, the patient reacted only to the rosin. The patient then remembered that for several weeks she had been taking esthetic dancing lessons and that rosin was sprinkled on the floor. She frequently sat on the floor to change her dancing slippers, using her hand to wipe the perspiration from her face. As long as she remained away from the dancing lessons her face remained well. We have subsequently discovered that substances containing rosin or resinous derivatives such as waxes, furniture polish, floor wax, automobile wax, etc., are occasional causes of eruptions.

The other patient was also a young girl who developed an acute dermatitis in the bends of the elbows and adjacent portions of the arms. Close questioning and patch tests finally revealed that the eruption was caused by ordinary brown wrapping paper covering some groceries which she had carried home from the store, holding the package in the bend of the elbow. A patch test with the wrapping paper produced a blistering reaction.

* * *

II. DIAGNOSIS

H. J. TEMPLETON, M. D. (3115 Webster Street, Oakland).—Four factors are to be considered when making the diagnosis of dermatitis venenata, namely, the morphology of the eruption, the location of the eruption, the patient's history, and the results of patch testing.

Morphologically, the clinical picture of dermatitis venenata varies from the transient erythema or chapping of the hands seen, following exposure to such irritants as gasoline up through the acute vesiculo-bullous eruption of poison oak to the thickened crusted fissured chronic dermatitis of the hands of painters who have been exposed daily to paints or turpentine to which their skins are sensitive. Therefore, we may say that there is no one uniformly typical clinical picture of dermatitis venenata. Probably the one most diag-

nostic picture consists of the streaks of vesicles produced where twigs of poison oak have brushed across the skin or where the same result has been produced by the spreading of the oleoresin by the patient's scratching.

The location of the eruption has been, in my experience, the most valuable diagnostic point. In general the lesions of dermatitis venenata have been limited to the face, neck, and arms, that is, as one would expect, to areas which could easily come in contact with external irritants. An acute eruption on the scalp might be caused by sensitization to quinin, or chloral in a hair tonic or to hair dyes. A dermatitis sharply limited to the upper half of the forehead would make one think of a hat-band dermatitis. The very common dermatitis of the eyelids should raise suspicion as to eyelash darkeners or cosmetics in general. Facial location immediately suggests that the dermatitis is due to powders, rouge, or cold creams. For example, a student had been the rounds of the dermatologists and allergists of the Bay district because of an intractable facial dermatitis which we had been unable to relieve. One day he burst into my consultation room almost shouting, "Doc, I've found it! Every time I go 'necking' my face breaks out." He was sensitive to orris root in his girl's face powder. Localization on the neck may mean sensitization to fur pieces, to painted beads, to scarfs. Dermatitis of the hands and arms generally means, I believe, sensitization to some external irritant. Cases have been reported of sensitivity to almost anything with which the hands come in contact. Housewives' dermatitis due to soap and water, the dermatitis of the surgeon due to scrubbing or to iodine or mercury, the dentist who is sensitive to novocain, the laboratory worker sensitive to formaldehyde, the nurse sensitive to denaturants (quinin, etc.) in rubbing alcohol, the painter sensitive to "turps," the florist or amateur gardener sensitive to primroses, chrysanthemums, or other flowers, the orange-stand girls sensitive to orange peel, the bank teller sensitive to nickle in coins—the list could be almost endless, drawn from one's own experience. A few bizarre locations and causes might be of interest. Location on the ear lobes and between the breasts pointed the way to diagnosis of a dermatitis venenata due to perfume. Dermatitis under garter clasps was proved to be due to nickle. A police officer developed a dermatitis under his upper vest pocket from irritation from a tear-gas tube. Similar to this is the frequently seen match-box dermatitis, which is situated under vest or pants pockets in which matches are carried.

The patient's history will often give the clue which discloses causes such as mentioned above. But in taking it one must be possessed of both patience and detective ability. One point, which I think is very important, has to do with a story of alternating periods of recovery and relapse. For example, if a patient states that his dermatitis began when he started work as a soda-fountain attendant, disappeared while on a vacation from such work only to relapse when he resumes his

duties, one would be especially inclined to consider the likelihood of the dermatitis being due to contact with something at the soda fountain.

Although not infallible, patch tests are of considerable value in diagnosing dermatitis venenata. Stripped of all unnecessary technicalities, this test simply means applying to a patient's skin the substance to which you think he may be sensitive and observing the result. Of course, if the substance is an irritant to any normal skin, it must be diluted with a nonirritating diluent down to the point where it will not irritate a normal control. All of the equipment that is necessary for the performance of the test is the substance suspected, pieces of cloth about one and one-half inches square, and rubber cement. A bit of primrose, a dab of cosmetics, a few drops of hair tonic or any other suspected substance is placed on the skin and covered by the cloth square, whose edges are fastened to the skin by the rubber cement. The patch remains in place for twenty-four hours, after which the skin is observed for evidence of erythema or vesiculation for several days. A positive test raises suspicion, but a negative test may mean only that the area to which the test was applied (generally back, thigh, or arm), was not sensitive, whereas the area involved by the dermatitis might have reacted vigorously had we dared apply the test at that site.

* * *

III. TREATMENT

HARRY E. ALDERSON, M. D. (490 Post Street, San Francisco).—The following recommendations apply only to the treatment of dermatitis venenata due to poison oak exposures. Naturally, dermatitis due to other contacts calls for entirely different measures. We have seen many cases of scabies and dermatitis due to other causes than poison oak that had been unsuccessfully treated with poison-oak remedies. In these cases the physician and the patient both cited their failures as proof that the plant toxin by mouth and by injection was of no use. Unfavorable criticisms of the method has been based often on wrong diagnoses and improper carrying out of the treatment. It must be remembered that individual skins differ greatly in their vulnerability and in their ability to recover promptly from an injury. This is seen in the very young, the aged, and in persons suffering from various metabolic disturbances. So local therapy has to be modified to meet the requirements of each case at different stages of the dermatitis.

In 1918, in accordance with Schamberg's suggestions, the writer of this article tried out the poison-oak toxin on a large number of cases at the Letterman General Hospital in San Francisco.¹ An alcoholic extract made from the leaves and twigs of the young plant was given by mouth and by intragluteal injection for curative as well as immunizing purposes. By giving the toxin in ascending doses, increasing tolerance for the poison was produced. This method had been carried out crudely by natives and Mexicans for many years, with more or less success. So popu-

¹ Alderson, H. E.: Notes on Skin Diseases Observed at the Letterman General Hospital, Calif. St. J. Med. (Oct.), 1920.

lar did the method become that concentrated and dilute solutions of the toxin for intramuscular and oral administration were placed on the market by at least six manufacturers.

Immunization Therapy.—By giving an intragluteal injection of the concentrated extract and then administering the dilute solution in daily ascending dosage for a month, a high degree of tolerance for the poison is built up. The dosage varies with the preparation. With the dilute alcoholic solution of poison oak it is customary to start with ten drops in water in the morning, eleven at noon, and twelve in the evening. In this manner the dose is increased by one drop each time until thirty drops are being taken three times daily. At this point we stop the drop dosage and give the preparation only once a day in two teaspoonfuls dosage. It is important to continue this for at least a month. Some very susceptible individuals take it all the time they are in poison oak territory. We have observed no ill effects, and believe that the occasional phenomena reported by others are most likely due to other causes. We can state that in our very extensive experience (from 1918 to date), we have never seen a case where we felt that a spread of the eruption could be attributed to this treatment.

Active Internal Treatment.—In the presence of an acute attack with much swelling and discomfort, we inject one cubic centimeter of the concentrated extract intragluteally and repeat in twelve hours if there is no relief. Rarely do we give a third injection. Frequently there is relief of the local symptoms within twelve hours, and after that, subsidence of the dermatitis is rapid. It must be remembered, of course, that underlying bodily conditions, and also the inherent tendency that some skins have to become eczematous when irritated by any agent, may prolong inflammation for some days after the poison oak dermatitis has subsided.

We realize that the injecting of the concentrated toxin in the presence of an acute poison oak dermatitis has not proper scientific foundation, but strikingly beneficial results are seen so often that they must impress one.² Dr. Merlin Maynard of San Jose has observed some good results in these acute cases from autohemotherapy. It is possible that we have here a "shock effect." However, I feel that the toxin is an important factor. Certainly, the itching and the inflammation are relieved early. As many of these patients are nervous, restless and itchy, it is occasionally necessary to give sedatives. Bromids, small doses of aspirin or of amytal (grain three-fourths) are very helpful. Naturally, rest in bed helps also.

Local Therapy.—As toxicodendrol is neutralized and dissolved by soaps, alkalies, and alcohol, early cleansing of the entire skin surface with these agents will render the poison on the surface harmless. At times patients have the mistaken idea that bathing is injurious and spreads the disease. Where lesions appear in spite of cleansing measures, it is because the poison has already

penetrated deeply enough to produce a reaction. Another prevalent mistaken idea is that fluid from the vesicles and bullae will spread the dermatitis. Inoculation experiments have proved that this is impossible.

Where there is much inflammation and edema, cold compresses of Burrow's solution, boric acid or magnesium sulphate solutions are very useful. When the edema is reduced, compresses of potassium permanganate aqueous solution (1-15,000) are recommended. As long as there is edema and exudation, compresses should be continued. Tincture of the chlorid of iron applications help the milder cases, but sometimes this produces annoying pigmentation. In the acute stages, greasy preparations are not desirable. The following lotions are beneficial:

R	Phenol	1.0
	Zinc oxid	16.0
	Lime water q. s. ad.	180.0
M.	Sig. Apply often.	
R	Resorcin	1.8
	Acid boric	7.0
	Alcohol q. s. ad.	180.0
M.	Sig. Apply and follow with talcum powder.	
R	Spirits of camphor	30.0
	Lotio calamin q. s. ad.	180.0
M.	Sig. Apply often.	

Dr. William Donald of Berkeley found, years ago, that application of liquid air on swabs would relieve the itching, and the inflammation would subside more rapidly afterward.*

As the inflammation somewhat subsides and the skin becomes dry, various ointments or liniments as used in eczema are indicated, as follows:

R	Juniper oil tar	1.5
	Lanolin	30.0
	Unguent zinc oxid q. s. ad.	60.0
M.	Sig. Spread on smooth cloths and apply.	
R	Menthol	2.0
	Liquor carbonis detergens	12.0
	Calamin liniment q. s. ad.	240.0
M.	Sig. Apply freely.	

The tar may be increased in amount if it is well tolerated.

Prophylaxis.—As stated in the first part of this paper, a high degree of tolerance can be developed by giving the dilute toxin ("immunizing solution") in ascending doses for a month or more. A hot alkaline bath, with plenty of soap and thorough dry cleansing of clothing worn when exposed, will eliminate most of the poison. An alcohol rub following the alkaline bath is recommended. As household pets running in the woods and fields may carry and retain the toxicodendrol for a long time on their hair, it may be well to have them thoroughly bathed. Another source of exposure is firewood and greens that are brought into the house.

While the toxin treatment is not 100 per cent effective, it is valuable in a very high percentage of the cases. Any treatment that is even 50 per cent efficient is worth while.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6.

ASSOCIATION ACTIVITIES

WPA MEDICAL SERVICE POLICIES

Latest information indicates that the following divisions of the WPA are directed through a central office in San Francisco.

- Resettlement Administrations.
- National Youth Administrations.
- Recreational Demonstrations.
- Work Camp Project, National Parks.

The WPA has no jurisdiction whatever over accidental injuries involving security workers employed by federal agencies such as the Army, Navy, Coast, and Geodetic Survey, even though these workers are certified by relief authorities or secured from the same sources that WPA workers are secured.

The department is governed by and operates under the rules and regulations of the United States Employees' Compensation Commission. The United States Compensation Commission and not the California Accident Board is the sole and final authority in instances of accidental injury.

Benefits arising through the Federal Compensation Act are extended solely to workers receiving *traumatic* injuries in the course of their work. Federal medical and surgical facilities must be employed wherever they are available.

When federal medical facilities are not available, then only licensed doctors of medicine may be called. The Commission recognizes only licensed physicians and surgeons.

The WPA has no closed panel of physicians and surgeons. All qualified, competent doctors of medicine are eligible to render service when federal facilities are not available. County medical societies are invited to designate competent members and this list is given to foremen for guidance when a surgeon is needed.

The Administration seeks to insure a fair and equal distribution of cases. It has no favorites. To accomplish

this impartial attitude each district compensation officer must keep and submit a cumulative report record of the number of injury cases treated by each doctor and the amount of each doctor's vouchers.

The Administration has had very few occasions for removing a doctor's name from the list of competent medical men. The chief cause for removal has been lack of cooperation in executing the paper work that is necessary and required by the Federal Commission.

Reports have come to us at rare intervals from individual doctors that their vouchers were disallowed. Investigation usually uncovers the following facts: The services rendered were not for a condition that resulted from employment or not received in the course of duty. A certain responsibility rests upon the doctor. He should know what cases and conditions are compensable. Knowing these, then, he should not charge his services to the Commission when the employee comes to him, even though the employee may present a WPA foreman's authorization for treatment for a cold. If doctors will become informed as to what constitutes compensable cases, there would be no difficulty regarding payment for services. The advice is to not expect compensation for services in cases and conditions not resulting from injury in the performance of duty.

Fees paid by the Federal Commission are not set up in any fixed schedule as far as medical services are concerned. The rule and precedent is to allow fees that are not in excess of the minimum charge in the community. The safe guide is to observe the fee schedule of the State Industrial Accident Commission.

The foregoing statements have been compiled from inquiries and investigations and are presented for the information of members.

COUNTY SECRETARIES' CONFERENCE

The annual conference of county secretaries was held in San Francisco on February 6.

The following secretaries, presidents, councilors, and state officers were present, numbering forty-seven:

STATE OFFICERS:

Edward M. Pallette, President
 Howard Morrow, President-Elect
 William W. Roblee, Speaker
 Morton R. Gibbons, Chairman of Council
 Karl L. Schaupp, Chairman of Executive Committee
 C. A. Dukes, Chairman of Committee on Public Relations
 Frederick C. Warnshuis, Secretary
 Calvert L. Emmons, Councilor
 A. E. Anderson, Councilor
 C. E. Schoff, Councilor
 Henry S. Rogers, Councilor
 T. Henshaw Kelly, Councilor
 J. B. Harris, Councilor
 Hartley F. Peart, General Counsel

COUNTY OFFICERS:

O. B. Doyle, Secretary, Fresno County Medical Society
 Merritt C. Canfield, Secretary, Imperial County Medical Society
 C. S. Compton, Secretary, Kern County Medical Society
 E. Vincent Askey, Secretary, Los Angeles County Medical Society
 S. K. Cochems, Executive Secretary, Los Angeles County Medical Society
 Carl W. Clark, Secretary, Marin County Medical Society
 A. L. Wessels, Secretary, Monterey County Medical Society
 F. D. Heegler, President, Napa County Medical Society
 Robert A. Peers, Secretary, Placer County Medical Society

*All articles listed under this caption, "This Month's Topics," have been written and sent to the Editor by the Association Secretary, Dr. Frederick C. Warnshuis.

R. M. Wallerius, President, Sacramento Society for Medical Improvement
 Arthur E. Varden, Secretary, San Bernardino County Medical Society
 Willard H. Newman, Secretary, San Diego County Medical Society
 Stanley H. Mentzer, Secretary, San Francisco County Medical Society
 Charles R. Kennedy, President, San Luis Obispo County Medical Society
 E. D. Anderson, Secretary, San Luis Obispo County Medical Society
 J. Garwood Bridgman, Secretary, San Mateo County Medical Society
 William H. Eaton, Secretary, Santa Barbara County Medical Society
 R. S. Kneeshaw, President, Santa Clara County Medical Society
 Leslie B. Magoon, Secretary, Santa Clara County Medical Society
 Samuel B. Randall, Secretary, Santa Cruz County Medical Society
 John W. Green, Secretary, Solano County Medical Society
 C. M. Carlson, Secretary, Sonoma County Medical Society
 E. F. Hagedorn, Secretary, Stanislaus County Medical Society
 Karl F. Weiss, Secretary, Tulare County Medical Society
 A. A. Morrison, Secretary, Ventura County Medical Society
 Francis P. Wisner, from Yuba-Sutter County

COMMITTEE ON POSTGRADUATE INSTRUCTION:

C. G. Toland, Chairman
 John C. Ruddock
 Langley Porter
 Paul S. McKibbin

COMMITTEE ON PUBLIC POLICY AND LEGISLATION:

E. T. Remmen
 Ben H. Read, Public Health League
 W. R. P. Clark

The scheduled program was observed. The opinion was unanimous that the conference would be productive of desired results that would broaden as well as intensify county society activity.

AMENDMENTS TO THE CONSTITUTION

At the 1936 Coronado meeting two amendments were submitted to our Constitution. Under the rules they come up for consideration and action at our 1937 meeting in Del Monte.

Delegates are advised to study these amendments and be prepared to express the wishes of their county when called upon to vote. The amendments are as follows:

1. *To make the retiring president a member of the Council by creating the office of past president.*

Resolved, That Section 1 of Article VII of the Constitution of this Association be and is hereby amended by inserting in the first paragraph thereof after the words "the president" the following:

"The past president"; and be it further

Resolved, That Section 8 of Article VII of the Constitution of this Association be and is hereby amended by inserting after the words "the president" the following:

"The past president"; and be it further

Resolved, That Section 1 of Article X of the Constitution of this Association be and is hereby amended by inserting after the words "a president" the following:

"A past president"; and be it further

Resolved, That Section 2 of said Article X of the Constitution of this Association and the title thereto be amended to read as follows:

"Section 2. President-Elect, when and how elected; term of office. Past president.

"The House of Delegates at the regular annual session thereof shall elect the president-elect to serve until the adjournment of the final meeting of the House of Delegates at its next regular annual session. At the conclusion of the final meeting of the House of Delegates at its next regular annual session, such president-elect shall assume the office of president, and serve as such for the term of one year thereafter, or until his successor assumes office.

"At the expiration of his term of office the president shall become the past president and serve as such for a

term of one year thereafter, or until his successor assumes office"; and be it further

Resolved, That Section 4 of Article X of the Constitution of this Association be and is hereby amended by inserting in the first paragraph thereof after the word "president" the following:

"Past president."

2. *Limiting appropriation of funds by the House of Delegates.*

Resolved, That Section 1 of Article XI of the Constitution of this Association be and it is hereby amended as follows:

By striking out all of the fourth paragraph of said Section 1 of Article XI, reading as follows:

"All resolutions providing for appropriations shall be referred to the Council, and all appropriations approved by the Council shall be included in the annual budget."

And by inserting in lieu thereof the following: "Any resolution passed and adopted by the House of Delegates at any regular or special session thereof, which provides for or contemplates the appropriation or expenditure of more than the sum of \$1,000, shall not be effective for any purpose unless and until approved by the Council. All appropriations, regardless of amount, approved and made by the Council shall, if expended, be reported to the House of Delegates at its next annual session, and any unexpended portion of any thereof shall be included in the annual budget.

ILL-ADVISED RESOLUTIONS

Defined policies, their observance and unity as well as uniformity of action begets organizational influence and results. In brief, the "house united" not only stands, but also endures as well as achieves.

Our Association has, through the House of Delegates, established definite policies and directed the attitude and action to be demonstrated.

From time to time some group—national or state, some business firm or some social uplifters—will gain the public limelight by advancing suggestions for or initiating a proposed plan or movement. At first glance or consideration there may become manifest some sporadic endorsement. Such endorsers usually fail to give careful consideration to pertinent facts, they are unfamiliar with all the details, they neglect to inquire from dependable sources as to the standing of the sponsors and fail to ascertain from the American Medical Association or from their State Association the information that may be on hand.

The American Medical Association and our State Association's Council run down what is back of these movements and proposals, and as a rule have complete information at hand. Often this information discloses ulterior objectives that are adverse to the members' best interest.

Ever and anon the report comes in that this or that county, hospital, or group have gone on record by passing a resolution of endorsement, when, had all the facts been known, no such endorsement would have been voted.

County societies will do well to refrain from granting endorsements until the information available has been secured from Association headquarters. Subsequent embarrassment can be prevented by making such inquiry. Members are assured that the officers and Council are alert and that they set out immediately to acquire facts whenever panaceas and new plans are projected. It is advised that endorsement be held in abeyance until all the obtainable information has been secured. In these days be wary of all proposals that announce a specific for social and economic ills. Rackets and racketeers still exist and new ones spring up regularly. Certain persons, business houses, and publications still like to pose as the "saviors of medicine"—but for selfish profit first. Black sheep are not extinct.

DEL MONTE ANNUAL MEETING

The April issue will contain the official program and announcements to be held in Del Monte, May 2-6. Watch for it.

In the meantime write now for your hotel reservations to Mr. Carl Stanley, Manager, Hotel Del Monte. Mr. Stanley has entire charge of all hotel reservations in Monterey peninsula. Advise him as to what accommodations you desire. Your wishes will be met if it is at all possible. On January 20 over 750 reservations were on file. This need not cause dismay, as ample accommodations are

available in first-class hotels adjacent to the official headquarters.

An excellent program, distinguished out-of-state guests, unusual scientific exhibits and demonstrations, a large commercial exhibit, and a most delightful program of entertainment should induce you to attend. Yes, there will be golf and skeet shooting. Secure your reservations.

OFFICERS AND COMMITTEES

Nearly every week inquiries are received requesting names of chairmen of committees or president or secretary of some county society.

This information can be secured by consulting the front advertising section of any issue of this publication. In that front advertising section, several pages for years have been devoted to the listing of officers, committees, scientific sections, county societies, their officers and meeting dates and similar information. Attention is directed to these pages of official directory material.

PARAGRAPH REMINDERS

Copy these in your engagement book.

1. Pay county society dues before April 1—preferably today, so as to escape being placed on the suspended list.

2. File Federal income returns before March 15; State income report before April 15.

3. Write to Mr. Carl Stanley, Manager, Del Monte Hotel, Del Monte, today for hotel accommodations around Monterey Bay for annual meeting, May 2-6. Mr. Stanley is in charge of all reservations.

4. Write to State Secretary for legal protection secured by membership in the medical society of the State of California.

5. Read the advertising pages and patronize these advertisers.

6. Watch for the April issue, which will contain the annual program for the 1937 annual meeting.

7. Become acquainted with your senator and assemblymen and ask your county secretary how you can aid in defeating undesirable pending legislation.

8. Tell your patients and friends to listen in on radio medical programs. Program hours are listed in the News section of each issue.

9. Apply to State Secretary for American Medical Association fellowship application blank.

10. Take your colleague or friend who is a nonmember to your next county meeting and urge him to apply for membership if he is eligible and desirable.

Get out your pen and book and note these important items. Do not, please, pass them up.

ONE THOUSAND DOLLAR FEES

From now on, under rulings of the Treasury Department, individuals paying professional fees in excess of \$1,000 must report such payment to the income-tax collector. Apparently, Uncle Sam proposes to check up on the income of lawyers, physicians, dentists, or others who charge fees for services rendered.

The suggestion has been that these charges or fees be billed at \$999 in order to relieve the recipient of your services of the necessity of making the return on his income-tax statements. Uncle Sam may spend billions freely, but he also is becoming alert in collecting every tithe or pound of flesh due to him. Evasion or the making of false returns is severely penalized.

SKEET CONTEST

Skeet shooters are requested to send to Dr. Alfred Phillips of Santa Cruz their intentions to enter into the Skeet Contest on Tuesday afternoon of our annual meeting in Del Monte. It is quite important that Doctor Phillips has this information in order that he can perfect local arrangements. All who desire to enter this contest will please advise Doctor Phillips at once.

COUNCIL MINUTES

Minutes of the Two Hundred and Fiftieth Meeting of the Council of the California Medical Association*

Held in the Sir Francis Drake Hotel, San Francisco, Sunday, February 7, 1937, at 9:30 a. m.

The meeting was called to order by the chairman, Morton R. Gibbons, with the following members present:

President Edward M. Palette; President-Elect Howard Morrow; Speaker William W. Roblee; Chairman Morton R. Gibbons; Councilors Karl L. Schaupp, Calvert Emmons, Henry S. Rogers, Henry J. Ullmann, A. E. Anderson, Alfred L. Phillips, Harry H. Wilson, J. B. Harris, T. Henshaw Kelly; Chairman of Public Relations Committee Charles A. Dukes; Editor George H. Kress; Secretary F. C. Warnshuis; General Counsel Hartley F. Peart and his associate, Mr. Hassard.

Absent: Doctors Carl R. Howson, O. D. Hamlin, and William H. Kiger, on account of illness; and C. O. Tanner.

1. **Annual Meeting.**—The Secretary presented a report on the program for the annual meeting as outlined by the Committee on Scientific Work at its meeting on January 9, stating that the invited guests for general meetings would be Cyrus Sturgis, Ann Arbor, Norman Miller of the University of Michigan, and Doctor Bullowa of New York. Doctor Meleney of New York will appear on a Medical Section program.

Doctor Warnshuis stated that the Committee wished to conduct a general meeting on medical economics at the third general meeting, having as speakers, Doctors J. B. Harris, T. Henshaw Kelly, and D. Crosby, and one invited guest.

It was moved by Editor Kress, seconded by Councilor Anderson that Dr. William C. Woodward of the Bureau of Legislation and Legal Medicine of the American Medical Association be invited to participate in the program on medical economics. Carried.

2. **Supplement to California and Western Medicine.** Editor Kress called the attention of the Council to his correspondence with the Los Angeles and San Francisco postmasters relative to possible supplements to CALIFORNIA AND WESTERN MEDICINE, and suggested the desirability of printing the Pre-Convention Bulletin and annual session program in such a supplement. Thus, for April, there would be printed the regular number for that month, and also its supplement containing the regular annual session information.

Upon motion by Editor Kress, seconded by Councilor Phillips, it was voted to print such a supplement, the Secretary to contact the San Francisco post office authorities in regard to fulfillment of all postal regulations of that office in regard to supplements. Carried.

3. **Legislation.**—Junius B. Harris submitted a report on legislation stating that 3,879 bills had been introduced during the first session of the legislature, of which 256 contained matters of medical interest.

After discussion of correspondence presented by Dr. Henry Rogers, on motion of Chairman of Public Relations Committee Dukes, seconded by Editor Kress, the disposition and action on the entire matter was left to the judgment of the Legislative Committee. Carried.

4. **Intercoast Hospitalization Insurance Association.** The General Counsel submitted revisions prepared for inclusion in the rider attached to the policies of the Intercoast Hospitalization Insurance Company which would make it acceptable to the California Medical Association.

On motion of Councilor Schaupp, seconded by Councilor Ullmann, it was

Resolved, That the Council approve the amendment to the standard hospitalization policy of the Intercoast Hospitalization Insurance Association presented to the Council by the General Counsel at this meeting (a copy of said policy and of said amendments having been this day filed with the Secretary); and be it further

* The minutes of the two hundred and forty-ninth meeting of the Council of the California Medical Association were printed in the February, 1937, issue of CALIFORNIA AND WESTERN MEDICINE, page 120.

Resolved, That the approval heretofore given to said policy by the Council be rescinded in the event that on or before March 15, 1937, said amendments are not adopted and put into effect as to all policies to be thereafter issued by Intercoast Hospitalization Insurance Association, and that a resolution be not adopted by the Board of Directors of Intercoast Hospitalization Insurance Association that all policies heretofore issued by it be interpreted by it, as far as possible, in consonance with said amendments.

5. Medical Society of the State of California.—A letter from Councilor Carl Howson regarding the possibility of increasing membership in the medical society of the State of California was presented. It was the sense of the Council that there should be no direct solicitation of members.

6. Committee of Five.—Correspondence regarding the present status of the report of the Committee of Five was presented and discussed in detail.

It was moved by Councilor Wilson, seconded by Councilor Ullmann, that the following communication be sent to the Director of the State Board of Health, Walter M. Dickie:

Dr. Howard Morrow presented Doctor Sharp's letter of February 3, 1937, to the Council of the California Medical Association.

I am instructed by resolution of the Council to inform you that we are now in a position to bring about the publication of the medical economic survey in California. The program is to submit the material for condensation and deletion of personalities, together with the securing of other mature opinion regarding conclusions and recommendations, as advised by Mr. Stuart Rice.

The California Medical Association to have an informed representative to meet with Doctor Sharp, Doctor Dodd, and one from your department, regarding the scope of this work.

It will require approximately ninety days for completion. Thank you for your coöperation in this matter.

It was the sense of the Council that a letter be sent to Dr. Olin West, Secretary and General Manager of the American Medical Association, requesting that Doctor Leland be permitted to assist in the evaluation of the report of the Committee of Five.

The Committee of Five was instructed to go over the report preparatory to submitting it to Doctor Leland, and in the meantime the authority would be requested from the American Medical Association for Doctor Leland's evaluation of the report.

It was moved by President Pallette, seconded by Councilor Phillips, that Dr. Alson Kilgore be appointed as representative of the Council in the conference (requested by Doctor Sharp) with Doctor Sharp and the Board of Health in regard to the publication of the Medical-Economic Survey Report. Carried.

7. Committee on Survey of Expenditures.—William W. Roblee, member of the Committee on Survey of Expenditures, submitted the report of the Committee, which was read section by section.

On motion duly made, seconded and carried, the Chairman was instructed to appoint a Committee of Three to investigate and provide for termination of services of employees of the Association, and submit a report at the next meeting of the Council.

It was moved by Councilor Kelly, seconded by Councilor Anderson, that no expenditures should be made for legislation without the approval of the Chairman of the Committee on Public Policy and Legislation and the Chairman of the Auditing Committee. Carried.

It was moved by Editor Kress, seconded by Councilor Rogers, that a copy of the report of the Committee on Survey of Expenditures be sent to each member of the Council for his information. Carried.

The Council discussed the question of publication costs of the JOURNAL.

On motion of Editor Kress, seconded by Councilor Kelly, it was moved that the Chairman of the Council appoint a committee of three well-known printers to go over the cost sheets of CALIFORNIA AND WESTERN MEDICINE in the offices of the Barry Company and to make a report thereon to the Council. The Chairman of the Council to appoint the said committee of three printers, these

to be selected from well-known printing firms of San Francisco and Los Angeles. Also the Secretary and the Editor to prepare a set of specifications as to publication and distribution requirements of the official journal, and to present the same for consideration to the Council at its next meeting. Carried.

It was brought to the attention of the Council that no change in the policy of advertising matter on the JOURNAL front page could be made until the former action of the House of Delegates was again considered by that body.

It was moved by Councilor Ullmann, seconded by Councilor Wilson, that the report of the Committee on Survey of Expenditures, excepting those portions which were acted upon individually, be received and filed for future consideration. Carried.

8. Budget.—Karl L. Schaupp, Chairman of the Auditing Committee, presented the budget of the Association for the year 1937-1938.

Discussion was had of the allocation of dues of members to the JOURNAL, and on motion of President Pallette, seconded by Councilor Phillips, the previous action of the Council taken on September 7, 1935, allocating \$3 dues per member to the JOURNAL was reaffirmed. Carried.

It was moved by Councilor Kelly, seconded by Councilor Phillips, that the Council instruct our auditors to set up the books of the Association on a nonprofit basis. Carried.

It was the sense of the Council that the budget be referred to the Auditing Committee, who, with the auditors of the Association, shall make the necessary changes and resubmit the budget at the next meeting of the Council at Del Monte.

9. Recess.—At this point a recess of the Council was taken for luncheon.

10. Call to Order.—The Council was called to order by the Chairman, with the following members present: Doctors Pallette, Morrow, Roblee, Gibbons, Schaupp, Emmons, Ullmann, Anderson, Phillips, Rogers, Harris, Kelly, Dukes, Kress, Warnshuis, Mr. Hartley Peart, and Mr. Hassard.

11. Venereal Disease Control.—After full discussion of the campaign for venereal disease control and legislation in relation thereto, on motion of Councilor Kelly, seconded by Councilor Ullmann, it was

Resolved, That the Legislative Committee be instructed by the Council to support legislation for the control of venereal disease that is satisfactory in the judgment of the Committee and that is also supported by the State Board of Health.

12. San Diego Fair.—The Secretary stated that a moving picture had been prepared by Doctor Foord for use at the San Diego Fair at an expense of \$250 and that it had been impossible to use it on account of lack of sound apparatus. That the Chairman of the Exhibit Committee had advanced the cost from his personal funds. It was pointed out that it might be possible to dispose of the film to the American College of Surgeons or the American Society for the Control of Cancer.

It was moved by Councilor Ullmann, seconded by Councilor Kelly, that the Council authorize the payment of \$250. Carried.

13. Past Presidents.—It was moved by Councilor Kelly, seconded by Councilor Phillips, that the honorary certificate for past presidents as presented by the Secretary be approved and that one such certificate be presented to each living past president at the time of the Del Monte meeting, and a certificate be presented to each future retiring president. Carried.

14. Tuberculosis.—It was moved by Councilor Kelly, seconded by Councilor Schaupp, that the Secretary be authorized to take part in the symposium on publicity sponsored by the State Tuberculosis Association at its Riverside session. Carried.

15. Retired Memberships.—The Secretary presented membership data and requests for granting of retired memberships to members of the following county societies: Etta Farmer, Sacramento County; Charles Edward Hablutzel and Charles Shattinger, Santa Clara County; Marie A. Bennette and H. O. Beeson, San Bernardino

County; Sol Hyman and Mariana Bertola, San Francisco County.

It was moved by Councilor Kelly, seconded by Councilor Harris, that Etta Farmer, Sacramento; Charles Edward Shattinger, Charles Hablutzel, Santa Clara County; Sol Hyman and Mariana Bertola, San Francisco County, be granted retired membership in the California Medical Association. Carried.

It was moved by Editor Kress, seconded by Councilor Phillips, that the Secretary be instructed to present to the Council at its next regular meeting a report on possible amendments having to do with retired and honorary memberships. Carried.

16. Annual Session Reporting.—It was moved by Editor Kress, seconded by Councilor Schaupp, that the bid of the Yates Reporting Service for the annual meeting at Del Monte be accepted for one original and two carbon copies of minutes of the House of Delegates and general sessions.

17. Listing in Journal.—A request from a special society for publication of its name in the JOURNAL, under Miscellaneous Organizations, was presented and the limitations of space discussed.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Ullmann, that the Council does not see its way clear to grant this listing at this time. Carried.

18. Hospital Standards.—After discussion of the question of standards of practice in certain hospitals, it was moved by Councilor Kelly, seconded by Councilors Ullmann and Emmons, that the Council of the California Medical Association does not approve attendance by members of component county societies in hospitals which permit other than doctors of medicine and dentistry licensed to practice in California to practice in the hospital. Carried.

19. Committee of Five.—It was moved by President Pallette, seconded by Councilor Rogers, that the Council rescind the action taken at its meeting on January 16, 1937, authorizing publication of 250 copies of the report of the Medical Economic Survey. Carried.

20. Date of Council Meeting.—It was moved by Councilor Schaupp, seconded by Councilor Phillips, that the next meeting of the Council be held at Del Monte, California, at 8 p. m., May 2, 1937.

21. Committee on Hospital and/or Medical Insurance.—T. Henshaw Kelly, Chairman of the Committee on Hospital and/or Medical Insurance gave a detailed report on amendments proposed by the dentists to the Association's bill for medical service, and other suggestions made for improvement of service offered by the bill.

It was moved by Councilor Ullmann, seconded by Editor Kress, that when amendments to the Association's medical service bill, and to the bill on hospital insurance are submitted by other interested parties, the Committee on Public Policy and Legislation and the Committee on Hospital and/or Medical Service Insurance be authorized to exercise its judgment as to the acceptance and support of such amendments. Carried.

22. Board of Health.—The question of personnel of the State Board of Health was discussed, and on motion of Editor Kress, duly seconded, the matter was referred to the Committee on Public Policy and Legislation. Carried.

23. Adjournment.—There being no further business, the meeting adjourned at 4:30 p. m.

MORTON R. GIBBONS, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

Progress in medicine is progress in science, and progress in science is progress in civilization.

It is an old saying that chance comes only to the minds that are prepared to welcome it.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

Legislation

As Dr. J. B. Harris, Chairman of the Committee on Legislation and Public Policy, stated at the Secretaries' Conference, the present session of the legislature would outdo all previous sessions in the number of bills and resolutions introduced. At the close of the first part of this session some 3,879 bills were filed. Some eight per cent, or 256 bills, are related or deal with health, medical practice and care, hospitals and health and hospital insurance.

An early tabulation indicates the purpose and form of proposed enactments.*

Supporting sound desirable legislation and opposing un-sound measures is not the sole duty or job of a chairman, committee, or officer. It is the duty and job of every one of our 5,500 members. Every county society and every member must enter into this legislative activity and respond to the directions and requests of our Committee on Legislation and Public Policy—the State Commanders. Members must not shirk, must not withhold action during the remainder of this legislative session.

It Is Happening Elsewhere

Wisconsin medical men find themselves in the throes of legislation that purposes to set up a system of insurance to provide medical and hospital care through compulsion. The present governor was elected, it is said, on that platform. It is reported that a "count of noses" indicates sufficient votes to pass such a law. Wisconsin will probably be the first state to enact this type of legislation, and as it is understood the medical profession will have no voice in control or direction. But a few years ago certain Wisconsin physicians were in a tirade and vocative expressions of disapproval because the California profession was confronted with a similar situation and condemned our Association and its officers because we were accused of inactivity. Compulsory health insurance laws are not on California's statute books. What is more, the Assembly Interim Committee on January 26, 1937, filed its report declaring "that the enactment of compulsory health insurance laws during the present session would be premature and ill-advised." The Committee recommended further study and report in 1939.

New Mexico is confronted with a situation similar to Wisconsin.

Minnesota finds the question a vital one during the present session of its legislature.

In Ohio, cultists are aggressive in an attempt to obtain broader regulations and recognition.

It is happening!

Medical and Legal Professions

The medical and legal professions have much in common. They have a joint relation to a large number of social and legislative movements and problems. On the other hand, there exists an interprofessional relationship and responsibility that has not been satisfactory at all times. Misunderstandings have frequently arisen mitigating against the welfare of members of both professions as well as the public.

The medical profession is well organized. The Bar Association functions for the legal profession. Both are representative and speak with authority for their professions. There exists, then, no good reason why these two organizations cannot, through designated representatives,

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

* EDITOR'S NOTE: See page 205 for list compiled by Committee on Legislation and Public Policy.

meet for the discussion of common interests, the adjustment of differences, the elimination of questionable practices, and the adoption of policies and procedures.

Such interchange of thought during prearranged meetings would accomplish desirable results and terminate differences. Salutory influences would become manifest.

To accomplish these ends it is hoped that some action will be taken at Del Monte that will bring about a series of meetings between the representatives of these two professions. The time is at hand when steps should be taken to obtain these ends.

Syphilis

Surgeon-General Parran has aroused nation-wide interest in a campaign for the reduction of the incidence of venereal infection—syphilis and gonorrhea. Publicity is increasing, and medical and lay groups are lining up in support of the movement. A warning was sounded by the Council when it adopted the following resolution:

Resolved, That the Legislative Committee be instructed by the Council to support legislation for the control of venereal disease that is satisfactory in the judgment of the committee and that is also supported by the State Board of Health.

This campaign, to be successful, must be fought out, as is any battle, under planned leadership—national, state, and county. Sporadic, independent and disassociated action should not be initiated in any community or region. All local activity should conform to the State plan and program adopted by the State Department of Health, with which department our Association is cooperating through a special committee, of which Dr. Howard Morrow is chairman.

COMPONENT COUNTY MEDICAL SOCIETIES

MARIN COUNTY

The Marin County Medical Society held its January meeting at the Marin Golf and Country Club. Dr. Anne Brady, the incoming president for 1937, was inducted into office.

Dr. Laurence R. Taussig gave a very interesting talk on *The Usual Skin Conditions as Met with by the General Practitioner*. The talk was illustrated by colored slides.

CARL W. CLARK, *Secretary*.

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was called to order by President Raymond Wallerius at the auditorium on Twenty-eighth and L streets on January 26. There were thirty-eight members and guests present.

The scheduled speaker of the evening, Dr. R. G. Leland, was unable to attend. In his absence, Mr. A. F. Henning, managing director of the local Retail Credit Association, gave an interesting talk on the *Economics of Credit*. Mr. Henning stated that there are about 400,000 credit cards on file at the Association; that 60,000 claims have been filed by professional men in the past ten years, of which 49.8 per cent were salvaged. The elimination of credit waste is the main endeavor of the Retail Credit Association, he said. The paper brought forth considerable discussion by the members.

A report on the passing of Dr. A. K. Dunlap was read by Dr. F. Scatena. A resolution was passed that the report be placed on the minutes of the Society and a copy be sent to the widow.

Doctor Soutar gave a report on the prevalence of influenza among school children, and asked that physicians report any cases found in their practice.

Doctor Turner discussed the matter of fees for testimony in legal cases, and stressed the fact that many physicians are not collecting for these services as they should. He also advised that the Board of Directors adopt a new fee schedule at their next meeting if possible.

Doctor Cook gave a report on the results of tuberculin testing in the city schools. Of the 1,297 students tested

at the high school, 358 (30 per cent) were found to be positive. Five of the adult type of active tuberculosis were found.

G. E. MILLAR, *Secretary*.

SAN JOAQUIN COUNTY

The regular meeting of the San Joaquin County Medical Society was held in the Medico-Dental clubrooms on January 7 at 8:30 p. m. The meeting was called to order by Vice-President A. L. Van Meter.

Preceding the regular meeting the customary supper meeting was held at the Hotel Wolf, at which fifteen members and guests were present. The paper at the supper meeting was given by Dr. G. H. Rohrbacher, who spoke on the *Battle of Gettysburg*.

The regular meeting was opened by Dr. C. A. Broadus, talking on the work of the Postgraduate Committee and their plans for the future.

Vice-President A. L. Van Meter installed President-Elect Dr. J. F. Blinn, who carried the meeting on from this point.

Doctor Hull brought up the question of a meeting between the Medico-Dental Society and the San Joaquin County Medical Society on the evening of January 25, on the occasion of Doctor Leland's visit to us. This was discussed by several members from the floor, and Doctor Broadus made a motion, seconded by Doctor Collis, that there be a joint meeting held on the above date.

Doctor Chapman spoke of the desirability of contacting the legislators at Sacramento from this district to try to impart to them our opinions of impending legislation. Doctor Sanderson made a motion, seconded by Doctor Collis, that a committee be appointed to plan ways and means for this contacting. The motion was carried. Doctor Chapman was appointed chairman of this committee, the committee to be announced later.

Doctors Van Meter and Sanderson spoke in favor of the \$5 a year increase of dues that the California Medical Association has instituted.

The petition of Doctor Hidy of Manteca having been accepted by the Committee on Admissions and there being no opposition from the floor, Doctor Hidy was elected a member. The petition for transfer of Dr. Paul A. Werthmann was received and read. There being no opposition from the floor, Doctor Werthmann was elected a member. Petitions for membership were received from Dr. T. C. Russell of Tracy, Dr. E. S. Leavenworth of Brentwood, Dr. Oliver Riggle of Lodi, Dr. Paul R. Shumaker and Dr. W. G. Patton, both of Stockton, were received and read. These petitions were referred to the Committee on Admissions for approval and recommendations.

A motion was made by Doctor Broadus, seconded by Doctor Van Meter, that potted plants be sent Doctors Thomas O'Connor and Kaplan, also letters of sympathy regarding their sickness. The motion carried.

The scientific program was given by Doctor Vieira, who announced that Dr. O. W. Jones of San Francisco was sick with influenza and would be unable to present his paper. Dr. Howard Brown of the University of California talked on *Spinal-Cord Tumors*. This talk was well received and caused considerable comment.

There being no further business to come before the Society, the meeting was declared adjourned at 10:30 o'clock and refreshments were served.

The regular meeting of the San Joaquin County Medical Society was held in the Roof Garden of the Hotel Wolf, Stockton, February 4, President John F. Blinn presiding.

The regular session was preceded by the customary supper meeting, at which fifteen members were present.

The paper at the supper meeting was given by Dr. G. H. Rohrbacher, who gave a demonstration of the modern medical equipment as used by the Army and National Guard. The regular meeting was called to order at 8:30 p. m.

The application of Dr. Elliott P. Smart from the Los Angeles County Medical Society for affiliation with this Society was presented to the members and approved.

Dr. H. S. Chapman reported on the progress of his committee which was to contact the legislators of northern California relative to health legislation.

Dr. C. A. Broadbudd made a motion, seconded by Doctor Van Meter, that the change in the by-laws relative to suspending members as requested by the California Medical Association, be referred to the directors for consideration, and their recommendations followed.

Dr. Dewey Powell made a motion, seconded by Doctor Van Meter, that the following resolution concerning the death of Dr. Thomas C. O'Connor be spread upon the minutes and a copy be sent to his widow. The motion carried.

IN MEMORIAM: THOMAS C. O'CONNOR, JR.

The members of the San Joaquin County Medical Society were shocked and grieved to learn on the thirteenth day of January, 1937, of the tragic death of their immediate past president, Dr. Thomas C. O'Connor, Jr.

Doctor O'Connor was born in Stonington, Connecticut, on the fifteenth day of August, 1893. His pre-medical education was obtained at the University of Nevada. He was graduated in medicine from the University of California Medical School on the eleventh day of May, 1927, and was licensed to practice in this State in December of that same year. He was junior assistant of the Colfax School for Tuberculosis until 1929, at which time he accepted the position of medical superintendent of Bret Harte Sanatorium. He resigned from that post in the autumn of 1936, and was preparing to enter private practice in his specialty of chest diseases in the city of Oakland at the time of his death.

The members of this Society esteemed Doctor O'Connor very highly for his professional attainments. His counsel was sought and valued in the problems of diagnosis and treatment of chest diseases, and his ability as a director and administrator is best evidenced by the fine results that have been achieved and the present standing attained by Bret Harte Sanatorium. His enthusiasm for his work and his loyalty to organized medicine was best manifested by the many long trips he took to attend our meetings, to serve on committees and the Board of Directors, and by the efficient manner by which he presided over our deliberations during 1936.

Doctor O'Connor has left a lasting impression with his coworkers and friends, and we desire to herewith extend to his widow and daughter our sincere sympathy and to also have a copy of this resolution spread in full upon the minutes.

Doctor Hull made a motion, seconded by Doctor English, that a copy of this resolution be sent to the editors of each paper in this county. Motion carried.

The papers of the evening were submitted by Dr. Harold P. Hill, who spoke on *Influenza and Influenza Pneumonia*. A second paper was read by Dr. Charles W. Barnett of Stanford University, who substituted for Dr. Russell V. Lee, on *Control of Venereal Infection*. Both papers caused considerable comment.

President Blinn suggested that all those who had not contributed to the flood relief, place their contribution in the box on the table.

G. H. ROHRBACHER, *Secretary*.

TULARE COUNTY

The January meeting of the Tulare County Medical Society was devoted to business matters and the annual election of officers.

Dr. J. C. McClure, President, presided at dinner. There were present Doctors Guido, Rosson, Ginsburg, Preston, Parkinson, Wynn, Austin Miller, Weiss, McClure, A. E. Anderson, Fillmore, Lipson, Falk, Hill, Mathias, and Brigham.

District Councilor A. E. Anderson of Fresno discussed the proposed voluntary health insurance measure and read the proposed code which the councilors are to pass on.

A general résumé of the Society's activities for the year 1936 was given.

Local Society dues were voted to remain the same as in the past, thus making a total of \$25 for State and local societies.

The application of Dr. Lynn Smith of Springfield was read and he was unanimously elected to membership.

Election of officers for the year 1937 resulted as follows: Dr. R. C. Hill of Exeter, president; Dr. Austin Miller of

Porterville, vice-president; Dr. K. F. Weiss of Visalia, secretary-treasurer; Dr. Ray Rosson of Tulare, censor, 1940; Dr. J. C. McClure of Lindsay, delegate; Doctor Parkinson of Tulare, alternate.

KARL F. WEISS, *Secretary*.

VENTURA COUNTY

The regular monthly meeting of the Ventura County Medical Society was held at the Ventura Country Club on Tuesday, November 10, 1936, at 7 p. m.

Members present were: Doctors Shore, D. G. Clark, Strong, Drace, Barker, Hendricks, Osborn, Bardill, Gronhøvd, Mosher, and Morrison. Guests were: Doctors Ullmann and Moffat.

Doctor Ullmann spoke briefly on the impending state legislation, stressing particularly hospital insurance and the necessity for immediate action. Doctor Ullmann suggested that we appoint legislative and insurance committees.

Dr. D. G. Clark introduced Doctor Moffat of Santa Barbara, who presented a paper on *A Patient with Extreme Obesity, Amenorrhea, Hypertension, and Diabetes* (case report). The patient was successfully treated with anterior pituitary sex hormones.

Business meeting followed.

Announcement was made of a postgraduate course to be given by the College of Medical Evangelists in Los Angeles. A similar announcement was made in regard to the College of Heart Symposium in San Francisco.

The State Secretary's monthly letter was read.

The first reading of the amendment for disciplinary procedure was given by the secretary.

Dr. D. G. Clark made a motion, seconded by Dr. H. E. Barker, that we approve the Alameda County Hospital insurance plan. The motion was unanimously carried. The secretary was instructed to write a letter to secure data on the above plan.

The Ventura County Medical Society held its annual banquet and election of officers at the Saticoy Country Club on Tuesday, December 8, 1936.

Members present were: Doctors Shore, Coffey, Mosher, Gronhøvd, Armitstead, Felberbaum, S. Clark, C. Smolt, Barker, Homer, and Strong. Guests were: Dr. Dan Clark of Santa Barbara, Doctor Cashew of Carpinteria, Mr. Charles A. Son and Mr. Gallagher of the Industrial Accident Commission.

Following the dinner the meeting was called to order by President Shore.

Mr. Charles A. Son gave a talk on the relationship between the Industrial Accident Commission and the medical profession.

Resolutions regarding the unfair practices of the public health nurses in the handling of school children, and one condemning the inadequate facilities for the proper care of smears and cultures in the outlying districts, were sent to the County Health Officer. A copy of the latter resolution was also sent to the Board of Supervisors.

Discussion was held in regard to establishing a minimum fee schedule for the county. No definite action was taken in regard to this measure.

Discussion was held in regard to the vaccination of children in the Ventura schools. Since this was a local problem, it was decided to let the physicians of that community reach their own solution.

A second reading of the amendment for disciplinary procedure was given by the secretary.

The following officers were unanimously elected for the coming year: Dr. F. R. Hendricks of Ventura, president; Dr. G. C. Drace of Ojai, vice-president; Dr. A. A. Morrison of Santa Paula, secretary-treasurer; Dr. G. C. Coffey of Ventura, delegate.

The Ventura County Medical Society held its regular monthly meeting at the Saticoy Country Club on Tuesday, January 12.

Members present were: Doctors Hendricks, Bardill, Shore, Drace, Barker, Mosher, D. G. Clark, Gronhøvd, Coffey, and Morrison. Guest: Doctor Eckhardt.

Following the dinner the meeting was called to order by President Hendricks.

President Hendricks read a résumé of the tentative bill to be sponsored by the California Medical Association. Doctor Coffey made a motion, seconded by Dr. D. G. Clark, that we go on record favoring such an insurance plan to be sponsored by the California Medical Association. The motion carried. Doctor Shore suggested that this insurance be limited to the lower income groups.

Doctor Bardill made a motion, seconded by Doctor Shore, that members sending in cards and not attending the meeting were to be assessed \$1, unless the secretary is notified by five o'clock the preceding day. The motion carried.

A third reading of the amendment for disciplinary procedure was given by the secretary. Doctor Coffey made a motion, seconded by Dr. D. G. Clark, that the amendment be adopted. The motion carried.

Doctor Mosher made a motion, seconded by Doctor Barker, that we endorse the Roche plan of medical advertising through the American Medical Association.

Doctor Shore made a motion that Doctor Porter be accepted for immediate membership. The motion was seconded and carried.

The secretary was instructed to write letters to Doctor Homer and Doctor Illick, who are ill.

Doctor Shore is in charge of the program for February.

A. A. MORRISON, *Secretary*.

CHANGES IN MEMBERSHIP

New Members (42)

Alameda County.—George A. Bakke, David R. Hadden, George S. Irvine.

Fresno County.—Hugh Awtrey, D. H. Trowbridge, Jr. *Imperial County*.—T. T. Mitchell.

Lassen-Plumas-Modoc County.—John W. Moore.

Los Angeles County.—Ralph W. Avery, Grant Beckstrand, P. Conrad Casper, E. L. Christeson, Erle Henriksen, Phillip Levine, M. H. Nathanson, Charles H. Pettet, Helen E. Preston, Samuel J. Sills, Walter H. Wieman.

Merced County.—E. M. Soderstrom.

Orange County.—Luther C. Davison, John J. Montanus.

Sacramento County.—W. F. Lowe.

San Bernardino County.—Ernest Cadwell.

San Diego County.—Leonard C. Fry, Thomas S. Mooney, Clarence E. Nelson, Thomas S. O'Connell, James E. Reeves.

San Francisco County.—Lazarre John Courtright, Burt L. Davis, Jr., John A. Driscoll, John B. Fershtand, Elliot G. Schneider, Steven Frederick Slepnikoff, Kazue Togsaki, Teru Togsaki.

San Joaquin County.—E. A. Anderson.

San Luis Obispo County.—Henry Fenno Sawtelle.

Santa Barbara County.—Walter Marius Anderson, C. W. Henderson, P. F. Munch.

Transferred (4)

Edward W. Bulley, from San Mateo County to Merced County.

Sophie M. Loven, from San Francisco County to Kern County.

Marshall E. Porter, from Sonoma County to Ventura County.

Thomas A. Wong, from San Francisco County to Los Angeles County.

Resigned (5)

Jessie M. Bierman, from San Francisco County.

Herbert M. Every, from Sonoma County.

Mark Gerstle, Jr., from San Francisco County.

Asher D. Havenhill, from San Francisco County.

Thomas H. McGavack, from San Francisco County.

In Memoriam

Carey, Henry Benjamin. Died at San Francisco, February 4, 1937, age 61. Graduate of the Northwestern University Medical School, Chicago, 1905. Licensed in California in 1906. Doctor Carey was a member of the San Francisco County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

+

Denman, Claire H. Died at Berkeley, January 12, 1937, age 69. Graduate of Hahnemann Medical College and Hospital of Philadelphia, 1893. Licensed in California in 1907. Doctor Denman was a member of the Alameda County Medical Association, the California Medical Association, and the American Medical Association.

+

Dunlap, Albert Knight. Died at Sacramento January 19, 1937, age 47. Graduate of Jefferson Medical College of Philadelphia, 1916. Licensed in California in 1917. Doctor Dunlap was a member of the Sacramento Society for Medical Improvement, the California Medical Association, and a Fellow of the American Medical Association.

+

Ghrist, David Garrison. Died at Los Angeles, February 3, 1937, age 38. Graduate of Harvard University Medical School, Boston, 1925. Licensed in California in 1926. Doctor Ghrist was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

+

Lenker, Walter Dora. Died at San Bernardino, January 30, 1937, age 43. Graduate of the College of Medical Evangelists, Loma Linda, 1918, and licensed in California the same year. Doctor Lenker was a member of the San Bernardino County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Minaker, Andrew J. Died at San Francisco, January 16, 1937, age 60. Graduate of the Hahnemann Medical College of the Pacific, San Francisco, 1899, and licensed in California the same year. Doctor Minaker was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Renz, Carl. Died at Mill Valley, January 22, 1937, age 73. Graduate of the University of Tübingen, Tübingen, Germany, 1889. Licensed in California in 1893. Doctor Renz was a retired member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Sweet, Frank Dumont. Died at Long Beach, January 24, 1937, age 50. Graduate of Emory University School of Medicine, Atlanta, 1916. Licensed in California in 1917. Doctor Sweet was a member of the Los Angeles County Medical Association, the California Medical Association, and the American Medical Association.

+

Van Sickle, J. Russell. Died at Santa Monica, January 16, 1937, age 57. Graduate of Wayne University College of Medicine, Detroit, 1906. Licensed in California in 1925. Doctor Van Sickle was a member of the Los Angeles County Medical Association, the California Medical Association, and the American Medical Association.

OBITUARY

Thomas C. O'Connor, Jr.

WHEREAS, Thomas C. O'Connor, Jr., was one of our early and most valued members; and

WHEREAS, His untimely death has severed a close and valuable personal friendship as well as deprived us, individually and severally, of a sympathetic and genuinely scientific point of view toward the problems of the patient with tuberculosis; therefore be it

Resolved, That the Laennec Society of Northern California adjourn this regular meeting out of respect to his memory; and be it further

Resolved, That a copy of this resolution be spread upon the minutes and notice thereof sent to his family.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

State Board Meeting

The State Board met at the Hotel Leamington in Oakland Wednesday, February 10. The meeting was called to order by the president, Mrs. Andrew J. Thornton of San Diego. The following Board members answered to roll call: San Diego, Mrs. Willard Newman; Los Angeles, Mrs. Clifford A. Wright, Mrs. John V. Barrow, Mrs. Benjamin H. Sherman, Mrs. Mark Albert Glaser, and Mrs. Arthur J. Annis; San Jose, Mrs. John Hunt Shephard; San Francisco, Mrs. George H. Becker and Mrs. Frank H. Rodin; San Rafael, Mrs. Robert M. Furlong and Mrs. Harry O. Hund; Oakland, Mrs. Frank R. Makinson, Mrs. Hobart Rogers, and Mrs. Charles C. Hall.

Six county presidents were present: Mrs. F. J. Maggs of San Joaquin, Mrs. Charles Moore of Santa Clara, Mrs. J. C. Geiger of San Francisco, Mrs. F. C. Knox of Monterey, Mrs. C. W. Page of Alameda, and Mrs. Harry O. Hund of Marin.

Since last Board meeting, Monterey County has organized, and much interest and enthusiasm was reported. They are coöperating with the convention chairman, Mrs. John Hunt Shephard, in making the annual meeting a most enjoyable one. A record attendance is expected at the Del Monte meeting. Splendid reports were given by the chairmen of the different departments and the councilors.

At one o'clock a delightful social hour and luncheon was enjoyed in the Peacock Room of the Leamington Hotel. The luncheon table was beautifully decorated in spring flowers.

Following the afternoon session a tea was given at the home of Mrs. Charles C. Hall honoring the president, Mrs. Charles A. Dukes, a past president of Alameda County, and Mrs. Thomas J. Clark, Jr., past president of the State Auxiliary, presided at the tea table. Assisting in the dining room were members of the Alameda County Board of Directors, including Mrs. Frank Baxter, Mrs. T. Floyd Bell, Mrs. Helen Gleason, and Mrs. W. O. Solomon.

Component Auxiliaries

Alameda County

The January luncheon meeting of the Woman's Auxiliary to the Alameda County Medical Association was held at the Claremont Country Club on January 15.

†As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

Mrs. W. H. Sargent, past president of the State Auxiliary, as well as of the Alameda County Auxiliary, was the hostess of the day, and the decorations were in charge of a committee headed by Mrs. T. F. Bell.

The chief items of business were the presentation of the handbook for the new year and an announcement concerning the loan fund for medical students.

The handbook contains a brief history of the Association, a complete membership roster, and the recently amended constitution. It should prove a practical aid to the members in their work.

Letters from both the University of California and Stanford Medical Schools were read, acknowledging the receipt of the loan funds for this year. One has already been granted to a student, and the other is in process of allocation.

The speaker of the day, Dr. Mary Burch of Mills College, gave an interesting talk on *The Problems of Childhood*. Doctor Burch is a specialist in child guidance, so had much that was interesting to tell.

It was announced that at the February 12 luncheon the guest of honor and speaker would be Mrs. A. J. Thornton, President of the State Auxiliary.

Los Angeles County

The Woman's Auxiliary to the Los Angeles County Medical Association met at the Orthopedic Hospital on Tuesday, January 26, with 110 members present. The attractive table decorations of pansies and ferns proved the ingenuity of the capable Flower Committee chairman, Mrs. William M. Daniel, in this period of frozen gardens.

As the program was of particular interest and along the line of public thought in connection with the significance of the President's Ball, quite a number of guests attended.

Dr. Robert L. Carroll, orthopedic surgeon, gave a talk on infantile paralysis.

A demonstration of rehabilitation of handicapped children was given by presentation of a play by crippled children of the Orthopedic Hospital. Trained to emphasize the value of the voice rather than body action, these young actors performed so convincingly, though confined in wheel chairs, braces or casts, that they gave almost the feeling of normal motion without actually moving around the stage.

The Auxiliary voted to contribute \$25 to the Red Cross for relief of flood victims in the Middle West.

MRS. ROBERT L. CARROLL, *Chairman of Publicity*.

Marin County

The Woman's Auxiliary to the Marin County Medical Society was addressed on Thursday evening, January 28, at the Marin Golf and Country Club by Mr. Harry Sapper of Oakland on the subject of *Social Education and Progress*.

At a tea given at her home on Grand Avenue recently, Mrs. Harry O. Hund, president of the Marin County Auxiliary, was hostess to the doctors' wives of Marin and Sonoma counties.

Monterey County

It is with great pleasure we announce that Monterey has joined the ranks of the Woman's Auxiliary to the California Medical Association.

The first meeting was held in January at the home of Mrs. Garth Parker of Salinas. Officers were elected and plans made for the new Auxiliary.

Mrs. John Shephard of Santa Clara was guest speaker. Her talk helped us greatly, for we were anxious to know how we could be of service to our community and not merely a social organization, and Mrs. Shephard pointed out many ways in which we could definitely be of help.

The matter of greatest importance at the moment is the Del Monte convention in May. This gives us something definite to work for, in which we are all interested.

We hope to have Mrs. Andrew J. Thornton with us at our February meeting to discuss the convention plans.

The following list contains names of charter members and officers: Mrs. Lawrence Knox of Carmel, president; Mrs. Arthur Wessels of Salinas, vice-president; Mrs. John Gratiot of Pacific Grove, secretary; Mrs. W. H. Farr of Salinas, treasurer.

Mesdames A. A. Arehart, Raymond Rukke, J. P. Sandholt, Mast Wolfson, Monterey; L. P. Daylin, Gonzales; William Gratiot, H. Spencer Hoyt, Winton Swengel, Pacific Grove; R. O. Griess, James McPharlin, Werner Meyenberg, Garth Parker, L. E. Smith, Mrs. F. E. Wiebe, Salinas.

RUTH RHODES GRATIOT, *Secretary*.

✽

Orange County

The regular meeting of the Woman's Auxiliary to the Orange County Medical Association for February took the form of a luncheon meeting at Danigers Tea Room in Santa Ana on February 2. Twenty-five members were present. The meeting was the first "no host" one of this year, and a discussion was held as to whether to make all the meetings luncheon or not, but no decision was made.

Mrs. L. E. Wilson, a member of the Public Health Committee, spoke briefly on the *Social Security Act*.

A scholarship loan for medical students of Orange County was established to be taken care of through our local junior college.

No other important business was discussed.

The program was a book review by Mrs. Hiram Currey, one of our members, who reviewed Victor Heiser's *An American Doctor's Odyssey*.

MRS. EDW. LEE RUSSELL, *Publicity Chairman*.

✽

San Diego County

The regular luncheon meeting of the Woman's Auxiliary to the San Diego County Medical Society was held at the University Club. The president, Mrs. F. G. Lindemulder, presided.

Mrs. Elmo Crabtree made another appeal for *Hygeia* subscriptions.

Our honorary member, Dr. Frances P. Elliott, was introduced and she very graciously acknowledged the introduction.

Mrs. Gage Wetherell, Chairman of the Social Committee, announced that, in order to raise funds, six benefit bridge teas will be given February 9 at the homes of Mesdames Elliott Colby, R. Emerson Bond, Alex Lesem, Thomas Whitelock, Jr., R. H. Lundberg, and F. G. Lindemulder.

Mrs. E. H. Christopherson, Chairman of the Public Relations Committee, told of plans for the Health Education program to be given Wednesday, February 24, at the Y. W. C. A. The general subject of this meeting will be *What Is New in Medicine*.

March of Medicine was given in a one-minute report by Mrs. H. W. Dickerson and a five-minute report by Mrs. R. Emerson Bond.

Our state president, Mrs. A. J. Thornton, guest speaker of the day, gave us a brief history of the Woman's Auxiliary, encouraging us in our local and state work.

Mrs. Thornton's talk was followed by an amusing greeting from Mrs. Willard Newman, State Corresponding Secretary.

Meeting adjourned.

ELIZABETH R. BELFORD, *Secretary*.

✽

Santa Barbara County

The Woman's Auxiliary to the Santa Barbara County Medical Society held its January meeting on the 18th at the home of Mrs. Henry J. Profant in Mission Canyon.

The meeting was preceded by a delightful luncheon served buffet style. Twenty-four members were present. Five ladies from Santa Maria were a welcome addition

to our group, this being the first time that members from the northern part of the county have attended one of our meetings. Mrs. N. N. Brown, District Councilor, was to have attended the meeting, but was detained on account of illness.

Mrs. C. T. Roome, one of the judges of the Essay Contest, reported on the results of the contest. Five essays on *Immunization: Its Theory, Practice, and Results*, were sent in from the high schools and colleges of the county. First prizes of \$20 each went to Earl O. Homan of the State College and Doris White of the Santa Barbara High School. Second prize went to Norma Pratt, and third to Daniel Scher, both of the State College. The second prize was \$10 and the third \$5, and all of them will be awarded soon at assemblies in the respective schools.

It was decided that we would, as usual, give a prize of \$10 to the best all-round nurse in the graduating class of the Cottage Hospital, the prize to be given at the graduating exercises on January 29. Plans were discussed for the annual benefit bridge party, and it was decided to set the date immediately after Easter.

Mrs. Roome read the essay which won the first prize, which described in about 1,500 words the two theories of immunization as offered by Erhlich and Metchnikoff. This was followed by a brief history of vaccination and a review of the results as applied chiefly to smallpox. All were agreed that Earl Homan deserved the prize he had won, and it is expected that following the publicity of the awarding, more essays will be submitted another year.

MRS. H. E. HENDERSON.

✽

Santa Clara County

Report of the regular meeting of the Woman's Auxiliary to the Santa Clara County Medical Association.

The meeting was a luncheon held at the San Jose Country Club on February 8, forty-two members being present.

Honored guests and speakers were Mrs. Andrew J. Thornton, state president, and Mrs. Willard H. Newman, state corresponding secretary of San Diego. Mrs. Thornton painted a verbal picture of the history and organization of the medical auxiliaries, and stressed the importance of a well-functioning social and educational group.

A letter was read from the American Association of University Women inviting members of the Auxiliary to hear Dr. Leo Eloesser of San Francisco, recently returned from a three months' stay in Russia, speaking on *Medical Education, Care and Organization in the Soviet Union*.

Mrs. Charles E. Moore, president, announced March 6 was selected by the Auxiliary committee for an informal dinner dance to be held at the San Jose Country Club for members and their husbands.

Mrs. John Hunt Shephard, chairman of the State Auxiliary convention to be held at Del Monte in May, urged all members to take an active part in the various committees.

MRS. DANIEL BILKER, *Publicity Chairman*.

Treatment of Intestinal Toxemia with Castor Oil.—Schoenbaum and Moomaw show that the colon is the principal focus of infection in toxemia and should receive at least as much attention as the teeth, tonsils, and other structures. Many constitutional disturbances as well as those of the abdominal cavity have their origin in a toxic condition of the enteric tract. In this connection the author mentions nervous, hepatic, biliary, circulatory and respiratory disorders, anemias, rheumatism, arthritis, disorders of the skin, backache, and other disturbances. He says that the so-called normal flora of the intestinal canal may assume pathologic activities under favorable conditions. The colon bacillus is the agent most frequently responsible for nongonorrheal infections of the genito-urinary system. Measures aimed at the detoxification of a septic colon will often help in solving a difficult diagnostic problem. The theory of intestinal toxemia is supported by clinical experience. In discussing the treatment, the author presents evidence on the detoxifying effect of castor oil and its conversion product, sodium ricinoleate.—*Virginia Medical Monthly*.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11. Olin West, M.D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 3-6. F. C. Warnhuis, M. D., 450 Sutter Street, San Francisco, secretary.

Medical Broadcasts*

American Medical Association

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts, under the title, "Your Health." The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title "Your Health," was given October 13, 1936. The theme for 1936-1937 differs slightly from the topic in the first series, which was "Medical Emergencies and How They Are Met." The new series is built around the central idea that "one hundred thousand American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Blue network instead of the Red, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the health magazine, and three weeks in advance in each issue of the *Journal of the American Medical Association*.

The time of the broadcast is Tuesday afternoon, two o'clock, Pacific time.

San Francisco County Medical Society

A radio broadcast program for the San Francisco County Medical Society for the month of March is as follows:

Tuesday, March 2—KYA, 6 p. m.
Tuesday, March 9—KYA, 6 p. m.
Tuesday, March 16—KYA, 6 p. m.
Tuesday, March 23—KYA, 6 p. m.
Tuesday, March 30—KYA, 6 p. m.

Los Angeles County Medical Association

The radio broadcast program for the Los Angeles County Medical Association for the month of March is as follows:

Tuesday, March 2—KECA, 10:30 a. m., The Road to Health.
Saturday, March 6—KFI, 9:15 a. m., The Road to Health.
Saturday, March 6—KFAC, 10:15 a. m., Your Doctor and You.
Tuesday, March 9—KECA, 10:30 a. m., The Road to Health.
Saturday, March 13—KFI, 9:15 a. m., The Road to Health.
Saturday, March 13—KFAC, 10:15 a. m., Your Doctor and You.
Tuesday, March 16—KECA, 10:30 a. m., The Road to Health.
Saturday, March 20—KFI, 9:15 a. m., The Road to Health.
Saturday, March 20—KFAC, 10:15 a. m., Your Doctor and You.
Tuesday, March 23—KECA, 10:30 a. m., The Road to Health.
Saturday, March 27—KFI, 9:15 a. m., The Road to Health.
Saturday, March 27—KFAC, 10:15 a. m., Your Doctor and You.
Tuesday, March 30—KECA, 10:30 a. m., The Road to Health.

*County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Cancer Commission Pathology Conference.—The annual pathological conference, given under the sponsorship of the Cancer Commission of the California Medical Association, will be held at the Del Monte Hotel, Del Monte, on Sunday, May 2.

The program will include a full morning and afternoon session. The plan at present is to present short symposia upon various groups of tumors, with interesting cases interspersed through the meeting. It is hoped that reports on tumors exhibited at former sessions will be made.

All those desiring to present cases and slides are requested to return the same to the chairman of the committee, Dr. Z. E. Bolin, 490 Post Street, San Francisco, at their earliest convenience, accompanied by one hundred slides and a case history which is to be mimeographed. Those who wish to participate in the conference are requested to register with chairman of the committee as soon as possible.

As in previous sessions, there will be no provision made for microscopes. Please bring your own microscope.

Annual Meeting of the California Tuberculosis Association.—A symposium on silicosis by three visiting speakers will be presented at the opening session of the annual meeting of the California Tuberculosis Association at Riverside, April 2 and 3.

Dr. Leroy U. Gardner, Director, Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, New York, Dr. R. R. Sayers, United States Public Health Service, Washington, D. C., and Dr. Anthony J. Lanza, Assistant Medical Director of the Metropolitan Life Insurance Company, New York, will conduct the symposium. These sessions will be held on Friday morning, April 2.

A clinical session will be held Friday afternoon, at which time there will be papers presented as follows: "Bronchial Stenosis," Dr. Leo Eloesser; "Pneumoperitoneum," Dr. Harold Trimble and Dr. Buford Wardrip; "Bilateral Pneumothorax," Dr. Everett Morris.

On Saturday morning a second clinical session will be held. Papers will be presented on "Relationship of Trauma to Tuberculosis," by Dr. Munford Smith, and "Diagnoses of Tuberculosis of the Intestinal Tract" and "Differential Diagnosis of Diseases of the Chest."

On Friday afternoon there will be a sociological session with a paper on "Epidemiology of Tuberculosis," presented by Dr. Reginald Smart of Los Angeles, and a presentation of the problem of "Tuberculin Testing of High School Students" from the viewpoint of the medical profession, the health officer, the school administration, school physician, and the public health nurse.

A second sociological session will be held on Saturday morning, at which there will be a discussion of "Rehabilitation" and a symposium on "Public Relations." Papers will be presented on "Presentation of Health Material on the Radio," "Newspaper and Class Organs," "Speakers' Bureaus," "Silent and Talking Pictures." Discussions on this symposium will be led by Dr. F. C. Warnhuis.

The annual banquet of the Association will be held at the Mission Inn on Friday night, and the annual business meeting will be conducted at luncheon on Saturday.

The committee who have prepared the program is composed of Dr. R. H. Sundberg of San Diego, Mr. James G. Stone of Los Angeles, and the late Dr. Thomas C. O'Connor, Jr., of Stockton.

For other information, write to W. F. Higby, Executive Secretary, California Tuberculosis Association, 45 Second Street, San Francisco.

All physicians are cordially invited to attend this meeting.

New York Polyclinic Medical School and Hospital. Dr. Russell L. Cecil, professor of internal medicine at the New York Polyclinic Medical School and Hospital, gave a special afternoon lecture on Wednesday, January 13, on "Streptococcal Infections and Their Treatment."

The following program will be presented at the March meeting of the Polyclinic Clinical Society:

"The Vermiform Appendix: Its Physiology and Pathology" by Dr. H. A. Royster of Raleigh, North Carolina; "Carcinoma of the Breast," with sound films in color, by Dr. Herbert C. Chase.

Coming Conventions: Military Surgeons; Railway Surgeons; Orthopedic Surgeons.—The Association of Military Surgeons of the United States announces the appointment of Mr. Robert Lewin as director of its convention exhibits.

Mr. Lewin has very successfully directed the commercial exhibits of the American Association of Railway Surgeons and the American Association of Orthopedic Surgeons for a number of years. This year he is also directing the commercial exhibit held in conjunction with the International Fever Therapy Conference at the Waldorf-Astoria, March 29 to 31.

The commercial exhibits of the Association of Military Surgeons have been creating more attention each year, and the exhibitors have found this to be a highly profitable meeting.

Anyone desiring information in connection with the Military Surgeons 1937 convention to be held at Los Angeles, October 14 to 16, the American Association of Orthopedic Surgeons to be held at the Biltmore Hotel, Los Angeles, January 15 to 19, the American Association of Railway Surgeons meeting to be held September 21 to 22 at the Palmer House in Chicago, or the International Fever Therapy Conference, as above mentioned, should address Mr. Robert Lewin, 505 North Michigan Avenue, Chicago, Illinois.

What Happens to Medical Fees for Saving the Injured?—In the city of New York thousands of doctors draw very considerable fees from accident cases. These fees do not always come from the injured person, but oftener from the insurance companies. They are not always paid willingly or entirely, and are frequently subject to adjustment. Nearly 2,000 of such fees are in controversy in the city of New York, entailing a delay for the doctor in obtaining remuneration and for the insurance company in clearing its record.

But New York State is trying a new experiment for adjusting such fees equitably and expeditiously.

Inspired by the voluntary arbitration system of the National Bureau of Casualty and Surety Underwriters, the amendments to the New York Workmen's Compensation Act passed in 1935 contain a provision for the arbitration of disputes on medical fees.

The Compensation Insurance Rating Board, in conference with officials of the Labor Department and the American Arbitration Association, has worked out an administrative plan for making this provision effective. Under this plan the insurance carrier files an objection with the Industrial Commission, with which is also filed an agreement to arbitrate and to abide by the award which is signed by both parties to the dispute. The Rating Board then arranges for a hearing before four arbitrators, two appointed by each side from special panels of doctors that have been appointed for the purpose through the cooperation of the county medical societies. When the four arbitrators fail to agree on a decision, they select a fifth doctor whose decision then becomes final. It is anticipated that the questions arbitrated will involve not only the size of the doctor's fees, but also his competency and his disposition to follow ethical standards.

The *Arbitration Journal* (521 Fifth Avenue, New York) for January tells the story of this experiment, describes the law under which it is being made and the machinery for making such adjustments. The story is part of a symposium on Arbitration in Insurance, which portrays the whole picture of what the insurance companies and arbitration are doing to meet the problems which arise after an accident has occurred.

East Bay Hospital Conference.—The East Bay Hospital Conference, composed of all the hospitals on the approved list, as issued by the American College of Surgeons in Alameda County, held its annual meeting on January 21, at a luncheon at Peralta Hospital in Oakland.

At the election of officers which ensued, Ellard L. Slack, Superintendent of Samuel Merritt Hospital, Oakland, was elected to succeed George U. Wood, Superintendent of Peralta Hospital, Oakland, as president. Dr. Benjamin W. Black, Director of Alameda County Institutions, was elected vice-president, to succeed Miss Florence Klaeser, Superintendent of the East Oakland Hospital. Alfred E. Maffly, Superintendent of Berkeley General Hospital, was reelected secretary-treasurer.

"Giving Information to the Press," the standard code on this subject, recommended by the American Hospital Association, was adopted as a standard for all members of the Conference. Dr. Robert P. Legge, professor of hygiene and university physician of the Cowell Memorial Hospital at the University of California, spoke on "The Control of Venereal Disease" as outlined by Surgeon-General Parran, at a meeting of the United States Public Health Service held in Washington, D. C., on December 28.

Dr. Benjamin W. Black, Medical Director of Alameda County Institutions, spoke on the "Relationship of the County Hospital to the Voluntary Hospitals."

Rosenwald Fund Makes Grant for Medical Economics Study.—The Julius Rosenwald Fund has made a grant of \$165,000 over a five-year period, to the Committee on Research in Medical Economics, it was announced by Edwin R. Embree, president of the Fund. This committee has recently been incorporated in New York, with Michael M. Davis as chairman, the other members being Robert E. Chaddock, professor of statistics, Columbia University; Henry S. Dennison, president of Dennison Manufacturing Company, Farmingham, Massachusetts; Walton H. Hamilton, professor of law, Yale University, and director of Bureau of Research, Social Security Board, Washington; Elvin S. Johnson, director of New School for School Research, New York; Paul U. Kellogg, editor of *The Survey Graphic*, New York; Harry A. Millis, professor of economics, University of Chicago; Fred M. Stein, retired banker, New York.

The committee will have an Advisory Board, to be enlarged as required, the following physicians now being members: Doctors Samuel Bradbury of Philadelphia, Alfred E. Cohn of New York, Alice Hamilton of Washington, Ludwig Hektoen of Chicago, and Franklin C. McLean of Chicago.

This committee will conduct and assist studies in the economic and social aspects of medical care; will train personnel for this field; and, in cooperation with the medical profession and other agencies, will furnish information and consultation services in behalf of rendering medical care more widely available to the people at costs within their means. The committee will have headquarters in New York City.

Since 1928, Mr. Embree stated, "the Julius Rosenwald Fund has been actively at work with the aim of reducing the costs of medical services and of making them more accessible to people of small incomes. Now the organized medical profession, hospitals, and many industrial and governmental agencies are engaged in practical experiments in different parts of the country, organizing medical care to reduce costs or developing methods of getting these costs into the family budget.

"Hence there is now less need for the promotion of action than for the guidance of action through scientific and dispassionate studies. The Fund, therefore, welcomes the opportunity to make a grant of this kind to a committee of social scientists and business men, with a distinguished medical advisory board. With this grant, together with the grant of \$100,000 recently made to the American Hospital Association to promote voluntary hospital insurance, the trustees have terminated their department of medical services, believing that these two agencies will now carry forward vigorously the Fund's long-standing and successful work in this field."

Examination for Entrance into the Medical Corps of the Navy.—An examination for commission in the Medical Corps of the United States Navy and for appointment as internes in the Medical Corps of the United States Navy will be held, beginning May 10, this year. There are about fifty vacancies in the Corps to be filled. The examination will be held at all United States naval hospitals and the United States Naval Medical School, Washington, D. C.

Candidates for admission must be between the ages of 21 and 32 years at the *time of appointment*, graduates of or senior medical students in Class "A" medical schools only.

Those who are interested should write the Surgeon-General, United States Navy, Bureau of Medicine and Surgery, Navy Department, Washington, D. C., for further information in regard to the examination and the procedure to follow for them to appear before one of the examining boards.

Sewage Treatment Works in the East.—C. G. Gillespie, Chief of the Bureau of Sanitary Engineering of the California Board of Health, in a recent report stated:

"While on vacation in the East attending an engineering conference this month, the Chief of the Bureau took occasion to visit a number of the newer and larger sewage treatment and water treatment works in the vicinity of the Great Lakes and Washington, D. C. Of some sixteen sewage plants visited, ten are exceptionally large and nearly all of them have been built or under construction during the last three or four years at the following places: Minneapolis, Milwaukee, Chicago, Cleveland, New York, and Washington, D. C. These ten plants serve almost ten million people and handle from 1,000,500,000 gallons to 3,000,000,000 gallons of sewage daily. The figure represents approximately seven times the total sewage production in all of California. The investment in sewage treatment works is approximately \$65,000,000 and, in addition, there is the expense of sewage interception to reach the plants, amounting to even a larger sum. Daily operating personnel exceeds one thousand men.

"One may see in these plants, representing as they do the best wisdom of this day, practically all of the newer ideas in stream pollution abatement and sewage treatment. How experience pays is illustrated in the case of two plants of similar type and for similar purpose in one of these cities where the most recent plant saves in the neighborhood of \$7,000,000 over the cost of the earlier one.

"One cannot escape the impression that sewage treatment is now in a new era, utilizing monumental works inheriting much of the handiwork of the power plant and electrical engineer. In fact, many of the plants present the appearance of high-grade industrial enterprises surpassed by few industries in architectural embellishment and mechanical orderliness.

"Yet the impression remains that these cities have not been extravagant. The scope of works and provision for the future is consistent with the needs in each particular case. Thus, Chicago, with almost no stream for dilution, turns to activated sludge treatment, graded down, however, for the actual needs of effluent as nearly as it can be predicted. Cleveland and Milwaukee, on the other hand, with recreational lake fronts to preserve, go to the highest degree of treatment in their activated sludge plants. At the other extreme, Washington, D. C., with the broad Potomac to receive the effluent, stops at simple sedimentation. In between, fall Minneapolis and the Coney Island Plant of New York City, where the processes are intermediate in results and costs. Minneapolis drains its effluent to the Mississippi River, having a considerable summer flow, and capitalizes on it. The Coney Island Plant capitalizes on its length of outfall into the ocean to reduce the degree of its sewage treatment.

"Sludge disposal, always the bane of handling sewage, is being met on an increasing scale by filtering the water out of the sludge and incinerating the sludge cake at high temperature, the same as is done with garbage.

"Coming home to the tendencies in California, the aim is toward a higher standard on proportionately less money than is represented in these eastern plants. We would succeed better were our economic 'sights' raised a little higher so as to do the job more adequately."

Thirty-Third Annual Congress on Medical Education and Licensure.—This year's conference was held on February 15 and 16 at the Palmer House, Chicago. The program included the following papers:

MONDAY MORNING, 10:00

Ray Lyman Wilbur, M. D., Presiding

Report of the Council on Medical Education and Hospitals. Ray Lyman Wilbur, M. D., LL. D., Chairman, Stanford University, California.

The Regulation of the Professions in the Public Interest. William E. Wickenden, B. S., President, Case School of Applied Science, Cleveland.

The Price of Professional Liberty. Guy Stanton Ford, Ph. D., Dean, University of Minnesota Graduate School, Minneapolis.

The Medical School Survey. Herman G. Weiskotten, M. D., Dean, Syracuse University College of Medicine, Syracuse, New York.

✓ ✓ ✓

MONDAY AFTERNOON, 2:15

Reginald Fitz, M. D., Presiding

Report of the Survey to Individual Schools, William D. Cutter, M. D., Secretary, Council on Medical Education and Hospitals of the American Medical Association, Chicago.

Symposium on Cancer

Biology of Cancer. C. C. Little, Sc. D., Director, Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine.

Pathology of Cancer. Francis Carter Wood, M. D., Director, Institute of Cancer Research, Columbia University College of Physicians and Surgeons, New York.

The Teaching of Cancer. Frank E. Adair, M. D., Secretary, American Society for the Control of Cancer, New York.

✓ ✓ ✓

MONDAY AFTERNOON, 2:45

The Federation of State Medical Boards

James N. Baker, M. D., Presiding

Medical Licensure as Related to the Practice of Medicine. Edward H. Cary, M. D., Chairman, Committee on Legislative Activities of the American Medical Association, Dallas, Texas.

The Fallacy of Spinal Adjustment. Thomas J. Crowe, M. D., Secretary, Texas Board of Medical Examiners, Dallas.

The Doctor and the Narcotic Violator. R. L. Sensenich, M. D., Past President, Indiana State Medical Association, South Bend.

A Lawyer's Point of View on the Narcotic Problem. Herman B. Carlson, Director, Division of Law Enforcement, Iowa, Department of Health, Des Moines.

Some Medical Licensure Problems of Massachusetts. Edward A. Knowlton, M. D., Member, Massachusetts Board of Registration in Medicine, Holyoke.

✓ ✓ ✓

TUESDAY MORNING, 9:30

Joint Session of the Council on Medical Education and Hospitals and the Federation of State Medical Boards

James N. Baker, M. D., Presiding

Symposium on the Selection of Students

Primary Mental Abilities. L. L. Thurstone, Ph. D., Professor of Psychology, University of Chicago.

Measurement of Personality. E. K. Strong, Jr., Ph. D., Professor of Psychology and of Applied Psychology, Stanford University Graduate School of Business, Stanford University, California.

The Why, What, and How of the Medical Scholastic Aptitude Test. Torald Sollmann, M. D., Dean, Western Reserve University School of Medicine, Cleveland.

Symposium on Technique of Examination

Philosophical Comments on Examinations, Howard T. Karsner, M. D., Director, Institute of Pathology, Western Reserve University, Cleveland.

Fundamental Purposes, Methodology, and Techniques of Examining in Relation to Medical Education and Licensure. Ben D. Wood, Ph. D., Associate Professor of Collegiate Educational Research, Teachers College, Columbia University, New York.

The Essay Examination on the Spot. Robert P. Dobbie, M. D., Assistant Professor of Surgery, University of Buffalo School of Medicine, Buffalo, N. Y.

TUESDAY AFTERNOON, 2:15

Charles E. Humiston, M. D., Presiding

Medicine in Education. Max Mason, Ph. D., California Institute of Technology, Pasadena, California.
 Relation of the American Medical Association to the Certification of Specialists. Charles Gordon Heyd, M. D., President, American Medical Association, New York.
 Increase in the Number of Practitioners in the Country. Harold Rypins, M. D., Secretary New York Board of Medical Examiners, Albany.
 Graduate Instruction and the State Medical Association. Charles R. Scott, M. D., Twin Falls, Idaho.

MONDAY EVENING, 6:30

The Federation of State Medical Boards
Annual Dinner

Address: James N. Baker, M. D., President, The Federation of State Medical Boards of the United States, Montgomery, Alabama.
 Address: Licensure and the Organized Profession. Charles Gordon Heyd, M. D., President, American Medical Association, New York.
 Round-Table Discussion.

MONDAY AFTERNOON, 12:30

Central Council for Nursing Education

Luncheon for Lay Boards of Hospitals and Public Health Nursing Organizations.
 Address: How Nursing May Promote Interprofessional Relationships. Joseph C. Doane, M. D., Philadelphia.

Regulations of the California Department of Public Health for the Prevention of Syphilis and Gonococcus Infections.—It shall be the duty of every person who gives treatment for syphilis or gonorrhea to report in writing immediately to the local health officer within whose jurisdiction such patient is, on a card supplied by the State Department of Public Health, the patient's initials, sex, and date of birth.

The local health officer shall forward these reports to the State Department of Public Health at least weekly.

The physician shall keep a record by name and address of each patient treated.

The name and address of the patient shall be reported to the local or state health official to whom the attending physician is required to report such case, upon the special request of such official if in his judgment this may be necessary to prevent the spread of the disease to other persons.

Whenever any person suffering from syphilis or gonorrhea shall discontinue treatment while, in the judgment of the attending physician, he is capable of transmitting the disease to others, such physician shall report immediately such facts together with the patient's initials and date of birth to the local or state health official to whom the attending physician is required to report such case.

Records of any local department of health or of any local health officer or of any laboratory, clinic or other institution, relating to cases of syphilis or gonorrhea, shall be confidential except in so far as may be necessary to carry out the provisions of the law and these regulations.*

Hospital Convention at Los Angeles: Hotel Biltmore, April 12 to 15.—The eleventh annual exposition and convention of the Association of Western Hospitals, Association of California Hospitals, western conferences of the Catholic Hospital Association, and allied groups and sections, will be held on April 12 to 15 at the Biltmore Hotel, Los Angeles. The preliminary program announces the following:

1. "The Manifold Obligations of the Hospitals to the Public"

This session will be a searching study of how well you serve your communities. It will set standards of community service. It will tabulate your community responsibilities. It will emphasize the dignity to your profession.

The speaker will be an experienced hospital administrator able to drive home an inspirational message.

* See also article in Miscellaneous department, on page 212.

2. "Legislation and Hospitals"

A timely topic with the multitude of bills and laws confronting us. It is planned to stress this from the "lobby" or "pressure-group" viewpoint. Many pressure groups are already with us. Others may be expected. This session should be very instructive to hospital administrators interested in the legislative problems of hospitals.

We plan to have a specialist in government technique present this lecture.

3. "Group Hospitalization"

(a) Is it a fact or a fancy? Has prosperity removed the necessity for it? These questions will be answered by an able speaker who will come from a plan that is working successfully.

(b) What are the helps and hindrances to its broad scale development? What is the responsibility of private hospitals? These, likewise, will be answered by a recognized authority.

4. "The Interest of the Patient Is Paramount"

Economy and budget balancing have occupied the minds and energies of administrators for several years. It is time to check up on your quality of service. Do you pass muster on scientific and sanitation facilities? These are minimums of service. Do you recognize the peculiar psychology of patients? Do your employees conduct themselves accordingly? What services do you render beyond the minimums of scientific safety and proper sanitation? There are many you must provide to really meet the true spirit of rendering hospital care to the sick. The speaker will delve deeply into this subject and should cause many administrators to recognize and develop a new sense of dignity of service in our profession. The speaker will be chosen because of experience, ability, and an appreciation for the intangible elements of service.

5. "The Growth, Causes, and Cures of Malpractice Suits"

This has always been a grievous problem to hospitals. Recently there has been a serious growth of such litigation. Some damaging decisions have been rendered recently. It is a delicate, difficult problem affecting every hospital. This session will candidly study the hazards that exist, the methods of preventing accidents, the legal procedure required to protect your institution when not at fault.

Perhaps we shall stage a pseudo trial to bring out dramatically the points of danger in such a suit. Handled by capable attorneys it will drive home its message in a new potent manner.

6. "Employee Welfare in the Broader Sense"

Leadership is a trait vitally necessary in every hospital. In the spirit of leadership, we shall discuss the importance of employee welfare. How do judgment, tact, kindness grow? Hospitals render mainly service and it is a product made only from human ingredients. We need to evaluate anew the employees' importance. New consideration must be given to this problem. This is necessary to insure the proper spirit in service to the ill, and to insure against labor disputes. We wish to avoid unionization of hospital employees.

The speaker will be a national authority on the subject. Do not miss this session. It bids to be one of your biggest days, provoke much discussion, perhaps a real debate.

Round Tables.—Each General Assembly will be followed by a one-hour round table. In this hour many can participate. Able leaders will be drafted to lead this hour of personal discussion. It is the hope of the Committee that truths can be driven home, different points of view presented, and a well-rounded conclusion carried away with each delegate. Petty issues will be ignored and vital problems emphasized.

Sectional Meetings.—Without losing the good in general assemblies, sectional meetings are being arranged without schedule conflicts. Dietitians, nurses, social workers, Auxiliary members, trustees, accountants, engineers, housekeepers, record librarians, will have programs of merit on vital hospital problems.

Exhibits.—Space for exhibits is already sold out. This feature promises to be better than ever. The latest and best will be available for your scrutiny and instruction. In four days you can get first-hand knowledge that would take months except for this convention.

Eating Habits of Past Generations Affect Our Teeth.

The modern doctor is now as much concerned about what sort of patient has the disease as he is about what sort of disease the patient has, Dr. John A. Marshall of the University of California College of Dentistry, told the members of the Los Angeles County Dental Society at a meeting held here. This necessity of studying the patient to determine habits, past ailments and hereditary defects, is coming to mean more and more in the practice of dentistry, Doctor Marshall said.

Doctor Marshall pointed out that there is some foundation of fact in the supposition that the dietary habits of the Americans of a few generations ago are having their effect upon the present generation, particularly in respect to tooth health.

"The average American of 1800 was as ignorant of food values as he was of sanitation, physiology, or anesthesia. Dairy products, vegetables, fruit, fish, and so forth, were used sparingly or were not even thought of. Whether these past dietary derelictions have had any ill effect upon the present generation is difficult to prove. However, the great number of nutrition experiments that have been carried on throughout the world indicate that such supposition has some foundation of fact."

However, Doctor Marshall pointed out, it will be a hundred years or more before the full effect of present corrective dietary systems will become apparent in human teeth.

The speaker emphasized the thought that dental diseases are not merely local lesions, unrelated to the rest of the alimentary tract, nor are they merely local manifestations of systemic diseases. "They are both, and because they are both, the etiology, the prognosis, and the treatment will always be difficult," he said. "But unfortunately the results of dental therapy—surgical, operative, dietary, and medicinal—fall far short of what we would wish."

Smiths, Johnsons, and Eight Others.—The United States Social Security Board announces that the Smiths once more have proved their numerical leadership by being the most frequent of all the names among the millions of wage-earners who will have social security accounts for participation in the federal old-age benefits program, the Social Security Board announced recently in stressing the importance of assigning a specific number to the account of every worker.

Preliminary estimates, the Board states, indicate that ten names—the Smiths, the Johnsons, the Browns, the Williamses, the Joneses, the Millers, the Davises, the Andersons, the Wilsons, and the Taylors—will constitute more than 1,500,000 of the total number of workers who will participate in the federal old-age benefits program.

The Board's Wage Records Office is setting up accounts for approximately 294,000 Smiths, 227,000 Johnsons, and 164,000 Browns. These are followed closely by the Williamses with a total of 156,000; the Joneses, 147,000; the Millers, 137,000; the Davises, 123,000; the Andersons, 115,000; the Wilsons, 96,000; and the Taylors 81,000.

If numbers for the accounts were not used, it would be necessary to obtain elaborate information about each worker on every wage report to insure accuracy in recording wages, the Board states. The use of the number makes the maintenance of such a vast system of accounts practicable and permits the use of an application blank asking for only simple information.

Estimates of the number of persons with these ten names are based on the assumption that approximately 26,000,000 wage-earners would participate in the old-age benefits program. Employers' application forms for identification number (SS-4), on file with the Board as of January 15, show that the approximate number of persons now in their employ totals 26,024,938.

The Post Office Department's count of the employee applications on file in typing centers as of December 16 was 22,129,617. Since then a large number of additional employee's applications for social security account numbers have been received daily.

Western Branch: The American Public Health Association.—The Western Branch, American Public Health Association, will hold its eighth annual meeting in Phoenix, Arizona, April 13 to 15. The program will be devoted to discussion of public health matters of special interest to the West, and will present speakers of national and western prominence.

Inquiries should be addressed to Dr. George C. Truman, State Superintendent of Public Health, Phoenix, or to Dr. W. P. Shepard, 600 Stockton Street, San Francisco.

Golden Gate Bridge Fiesta.—The completion next May of the great Golden Gate Bridge, longest suspension span ever constructed, will be the signal for a spectacular four-day celebration in San Francisco, which promises to echo round the world.

Sweeping majestically across San Francisco's famed Golden Gate, through which the Argonauts first glimpsed the land of their golden hopes eighty-eight years ago, this gigantic bridge will be among the most impressively beautiful structures built by man.

The Golden Gate Bridge Fiesta, as the opening celebration will be known, is aimed to eclipse anything of its kind ever seen in the West, and plans already advanced call for a series of brilliant and colorful land, water and aerial pageantry, and other activities for four wondrous days and nights.

The celebration is to be international in scope, for the \$35,000,000 bridge will break the last major water barrier to the north of San Francisco and offer a continuous highway between Canada and Mexico via San Francisco and the Redwood Empire along the northern coast of California.

The Army and Navy have pledged the fullest coöperation for the celebration and every available warship in the fleet in Pacific waters will be assigned to San Francisco harbor for the duration of the festivities.

On bridge-opening night, the warships will focus their powerful spotlights on the span, which will also be brilliantly illuminated with flood lights suspended from the high towers. Colored bombs bursting in air, together with a mile-wide display of fireworks, will signalize the first formal illumination of the great bridge.

The Golden Gate Bridge, financed by public bond issues in San Francisco and five Redwood Empire counties, is even more spectacular than the state-operated and federal-financed San Francisco-Oakland bay bridge, which connects San Francisco with Oakland and cities on the east and which was opened last November.

As the highest and longest single span suspension bridge in the world, the Golden Gate Bridge has a main span of 4,200 feet and an overall length of 9,200 feet. The main span is 700 feet longer than the George Washington Bridge across the Hudson River at New York City, and the towers are 150 feet higher; the towers are also 191 feet higher than the Washington monument. The floor of the bridge is 250 feet above the seven-mile an hour tides that continually sweep in and out of the entrance to San Francisco Bay.

Construction of the pier 1,200 feet offshore from the San Francisco side in 100 feet of water was one of the most daring and unusual in bridge-building history, being the first bridge pier built in an open sea. The work of this pier was carried on inside a permanent steel and concrete "fender pier" 750 feet in circumference and 115 feet high.

The steel towers, extending 746 feet above mean high water, will serve as aerial beacons and possibly for radio broadcasting. There will be complete independent telephone, fire and police telegraph systems on the bridge. The annual capacity of the span has been estimated as seventy million passenger cars and six million trucks.

Construction of the bridge was begun in January, 1933, and the cost of \$35,000,000 will be paid from collected tolls. Joseph B. Strauss is chief engineer of the structure.

The Golden Gate Bridge Fiesta in May will be a forerunner of the Golden Gate International Exposition in 1939 to celebrate completion of both the San Francisco-Oakland Bay Bridge and the Golden Gate Bridge.

International Conference on Fever Therapy.—In conjunction with the International Conference on Fever Therapy to be held at the Waldorf-Astoria Hotel on March 29 to 31, there will be a scientific and commercial exhibit staged.

The clinics will be held at the College of Physicians and Surgeons, Columbia University, New York City.

A large attendance of fever therapists from all over the world is expected. A very interesting and instructive program has been arranged, and all of those who plan to attend the conference are urged to register promptly with the general secretary, Dr. William Bierman, 471 Park Avenue, New York City. The registration fee is \$15.

Monthly Statement of Venereal Diseases Reported in California.—The Treasury Department of the Public Health Service, in its December report, gives the following figures for California:

State and Cities	Syphilis		Gonorrhea	
	Cases Reported During Month	Monthly Case Rates Per 10,000 Population	Cases Reported During Month	Monthly Case Rates Per 10,000 Population
California	1,508	2.67	1,542	2.73
Los Angeles*			42	1.39
Oakland	45	1.48	147	2.19
San Francisco	152	2.27		

* No report for current month.

Social Security "Severance" Reports of Employees Leaving Service.—To insure eligible workers their full rights to benefits under the unemployment compensation provisions of the Social Security Act, the National Social Security Board has ruled that wage-earners shall not be required to sign "severance" reports. This is a form on which the employer reports to his State unemployment compensation administration when any employee subject to the law leaves his employ, giving the reasons therefor.

The purport of this ruling, which now becomes effective in the thirty-five states and the District of Columbia having unemployment compensation laws approved by the Board, will be to protect workers from being virtually forced into agreeing to postponement or possible loss of their unemployment compensation benefits. . . .

When Employer Voluntarily Pays Employees' Tax.* United States Commissioner of Internal Revenue Guy T. Helvering announced that amounts voluntarily paid as employees' tax by an employer, without collecting such amounts from his employees, are not wages subject to the taxes under Title VIII of the Social Security Act.

Title VIII of the Social Security Act imposes two taxes, an income tax on employees and an excise tax on employers, both of which became effective January 1, 1937. The initial rate of each of these taxes is one per cent of the wages of the employee. The law makes provision for the employer to collect the income tax on employees by deducting the amount thereof from the wages of each employee when they are paid.

After the close of each calendar month both the amount of the tax on the employer and, whether or not collected from his employees, the amount of the employees' tax must be paid by the employer to the collector of internal revenue. The taxes with respect to all taxable wages paid by the employer during a calendar month are required to be paid to the collector within the succeeding month. Form SS-1, the monthly return to be used by employers for this purpose, is available at the offices of all Collectors of Internal Revenue.

A number of employers have made known a desire to pay the employees' tax under Title VIII without deducting the tax from the remuneration of their employees. They have requested a ruling whether the amount so paid by them will itself be subject to the taxes under that title of the Act. The amount of the employees' tax in such case, if voluntarily paid by an employer, is not considered as additional wages subject to either the employer's tax or employees' tax imposed by Title VIII of the Act.

LETTERS

Concerning the fight against syphilis.

TREASURY DEPARTMENT
PUBLIC HEALTH SERVICE
WASHINGTON

January 28, 1937.

To the Editor:—I wish to thank you for your letter of January 15 and the copy of the January issue of CALIFORNIA AND WESTERN MEDICINE. Your editorial, entitled "The Fight Against Syphilis: Long Delayed, Off on a Good Start," has been read with considerable interest, and I hope, as you say, that the time is now ripe for a well-organized campaign and that the funds available through the Social Security Act will stimulate this work in State and local health departments.

Sincerely yours,

R. A. VONDERLEHR,
Assistant Surgeon-General,
Division of Venereal Diseases.

Concerning "throw-away" publications.

January 20, 1937.

To the Editor:—There is an increasing tendency of some so-called "throw-away" publications to reprint, without permission, material appearing in the more ethical medical publications.

At the last meeting of the Committee on Publication of the Official Journal of the Minnesota State Medical Association it was decided to formally notify such publications not to reprint any material from *Minnesota Medicine* without written permission from the Editor or the Committee on Publication.*

It is our opinion that if every recognized medical publication would take similar action, it would materially aid in correcting a practice that is both unfair and unethical. *Minnesota Medicine* is sending a notice to four such publications (Medical Economics, Modern Medicine, Current Medical Digest, and the New York Physician), by registered mail, return receipt requested, although we do not know at this time whether any of them have reprinted material without permission.

Very truly yours,

MINNESOTA MEDICINE.
C. B. DRAKE, Editor.

Concerning silicosis.

To the Editor:—The Medical Committee of the Air Hygiene Foundation of America, 4400 Fifth Avenue, Pittsburgh, Pennsylvania, headed by Dr. A. J. Lanza, Chairman, announces the completion of a comprehensive treatise on "Silicosis and Allied Disorders." The Committee has attempted to bring together in one report a summary of those phases of pneumoconiosis which have been the subject of research, those which have been settled more or less conclusively, and those demanding further investigation.

The report, designed for industrialists as well as physicians, offers a practical, six-point program of health control for the "dusty trades." Recommendations for research along four fundamental lines are submitted to the Foundation in the report. These researches represent those which the Committee agrees are most urgently needed at the present time to increase our knowledge of pulmonary diseases which may result from air pollution. . . .

The conclusion of the report is a summary, which follows:

The extensive studies of silicosis in this country and abroad have given us a very clear idea of the cause of this disease, its pathology, its complications, and its prognosis. On the basis of our present knowledge, it may be said that:

1. Silicosis results from the inhalation of dust containing free silica.

*All articles in CALIFORNIA AND WESTERN MEDICINE are copyrighted and cannot be copied or abstracted without permission of the Council.

2. The time required for the development of silicosis varies from a few years to twenty or more, depending on the concentration of silica particles in the air and the constancy of exposure.

3. Beginning silicosis is recognizable only by properly taken roentgen films of the chest; small nodular shadows distributed throughout both lungs are the characteristic appearance. There are no symptoms or physical signs associated with early simple silicosis which can be depended upon for making diagnosis.

4. Associated with silicosis is a marked predisposition to tuberculosis.

5. Silicosis can be prevented by protecting the industrial worker from inhaling silica dust. This may be accomplished by engineering measures.
